BUILDERS will do well to hesitate before they put in the phrase, "in the best possible manner," in the proposals they draw up when seeking work. In the Hereford County Court the words have caused judgment to be given against a builder, although there were doubts in the case. The plaintiff's house at Orcop was injured by a fire, and, as a result, he entered into a contract for work that might be called rebuilding. It was alleged that the rain came into the new house, the floors shrank, and generally the woodwork was unsatisfactory. But, in spite of the defects, the plaintiff paid the price agreed on, his excuse being that his neighbours were saying he was unable to pay. It was also admitted that the price paid was low. An architect was called in, and he said the work was "scamped" from beginning to end. The spaces between the floor boards were about $\frac{3}{8}$ to $\frac{1}{4}$ -inch wide. The chimneypieces were badly constructed, and unsafe. The joints in the stairs had sprung, and the wood split. The whole of the wood used for the doors was unseasoned, and the doors were of little use in keeping out the draughts and rain. Daylight could be seen through the slates, and the house was one mass of damp. Another architect, called on behalf of the builder, said he thought the work had been done according to the specification. The state of the floor could be put down to the season in which the work was executed. The specification specified a cheap job. He had seen evidences of wet having come in, but he thought it had entered during the time the snow was about. All buildings, however, would be liable to the same thing unless special provision were made. The judge said he should have thought that any defects which might have existed would have been discovered during the first winter, and action taken at latest in the following spring, but no doubt action was delayed because defendant looked to plaintiff as a friend. He thought, however, the specification was loose. No doubt builders were in the habit of putting in the words "in the best possible manner." There must be some meaning attached to them, but if not, the sooner they were left out the better. In giving judgment for the plaintiff, he said he must take into consideration that the estimate of what was required to be done was not made until about two years after the work had been completed, so he should therefore give judgment for 25*l.*, the usual costs to follow.

AMENDED building regulations were adopted in Chicago on the 13th inst. The greatest height allowed for buildings will be 130 feet instead of 160 feet. A department of city government, to be known as the department of buildings, embracing a commissioner, a deputy commissioner, a secretary, and such inspectors and other officers as the City Council may provide, is to be established. The commissioner is required to be an experienced architect, civil engineer or builder, and will hold office for two years. He is given the power of inspection over elevators, fire-escapes and all classes of buildings, and is required to establish rules and regulations for inspections and erection of structures. The inspectors are required to be skilled labourers, and before their appointment are required to pass an examination before a committee consisting of one member each from the Builders and Traders' Exchange, Building Trades Council, Underwriters' Association, and Illinois Chapter of the American Institute of Architects. The commissioner and inspectors are empowered to enter all buildings for the purpose of ascertaining whether the regulations have been complied with, and in case the department decides against the security of any work in process of construction, the persons interested are allowed an appeal to a board of arbitration. The power of the commissioner to take down and demolish dangerous walls is confirmed, and an amendment establishes a board of arbitration to act in certain cases.

ANTOINETTE VAN ROSEMAIL AND THE EARLY
FLEMISH REFORMERS.

OWING to the position of the Spanish Government the power of the Inquisition in the Low Countries was intolerable, and was enough to urge the people into opposition against any system of which it was an agency. As a consequence, not only burghers but women were driven to take part in an agitation for a reform of the Church. The Flemings still remember the influence of ANTOINETTE VAN ROSEMAIL, who was able to persuade not only monks, but scholars and men of science to co-operate with her, and there is no doubt her efforts had much to do with freeing the country from a foreign yoke.

IMPNEY, DROITWICH.

A VIEW IN BASLE.

THE ARCHITECTURAL ASSOCIATION.

THE ordinary meeting of the Association was held on Friday evening, Mr. Paul Waterhouse, M.A., in the chair. A vote of thanks was passed to Mr. Dellissa Joseph in connection with the last visit.

Mr. J. A. GOTCH read a paper as follows, entitled—

In Praise of a Country Practice.

Mr. Gotch said:—If you will tear yourselves away from the delights of London, shrouded, as they often are, in smoke and fog, I should like to place you in the windows through which I look every day of my life and show you a glimpse of some characteristic Midland scenery. Large undulations terminate the view on every side. In one direction the sombre tints of the earth are divided from the pale sky by the deeper hue of a distant wood. In another a white road winds out of sight over the shoulder of a gentle declivity, which permits a glance at the dim blue distance of the next county. On a third side one or two slender spires overtop the hills as they shoot up out of their masses of foliage; while straight in front of us, just across the valley which parts us from the town, rises the grey mass of the tower and spire of the parish church, with its battlements and turrets and crockets sharply defined against the sky. It is not merely in its beautifully tapered outline—unsurpassed by any spire in the land—in its crisp and vigorous delicacy, or in its curious angle turrets, that seem to be an echo of the defensive features of a castle—it is not only in these that its charm lies, but also in its ever-changing aspect, responsive to the changes in the atmosphere. Sometimes it thrusts its summit, dark and delicate, above the morning mist which hides all the lower part, together with the earth that supports it. Sometimes the hot summer sun picks it out with sharp shadows in front of the blue sky, leaving it still—sunlit though it is—darker than its peaceful background. And then again, sometimes—not often—the evening sun will paint it white against black, storm-laden clouds, lending it an almost terrible aspect, like the white lips of an angry face.

At its base, stretching away on either side, lies the town, red with red bricks and blue with blue slates, here and there in the older parts somewhat mixed with grey stone and largely mollified with trees. But as it recedes from the church the town grows redder and redder till at one end it stops with a mass of white-brick cottages that mark a newly-developed building estate, while at the other it breaks up into detached houses that show how the moneyed men are gradually building their way into the country. The town is no less interesting to us than the church, though in a different way, for there lies our work and there live our clients.

You who live and work in this great wilderness of London have but a faint idea of what it is to live among your work and among your clients. The vast journeys that separate you from the former half remove it from the realms of tangible reality. To you it is less a living fact than a kind of simulacrum on paper. Your decisions on unexpected matters of construction are often more or less theoretical, not dictated by the lively knowledge which an inspection on the spot imparts. You cannot watch its constant growth, brick by brick and stone by stone, and see your design slowly evolve itself, till the amorphous mass of the ground floor develops into articulate shape with the roofs. To you the building grows by leaps and bounds, and to some of you, perhaps, it never grows at all except as an abstract thing in mechanical drawings.

How much more difficult it is for those who pay only a flying visit now and again to their work to introduce those little touches which spring from, and harmonise with, local circumstances not observable till the building is partly built. How

much easier it is for those who can watch the effect of their mouldings from day to day to improve upon them as occasion arises, and to modify them to meet slightly altered conditions. For instance, if a string-course is hardly as effective as it should be, three steps will inform you how much the mason has worked—and he cannot have worked much since you saw him last—and a very little adjustment will probably enable you to use the disappointing member elsewhere, while a slight recasting of the detail will give all you desire. Or if a chimney-cap has not the delicacy of profile that you expected, before another one is worked you can remedy the defect; and all without waste of stone or hindrance to the work. Then, again, how valuable it is to spend ten minutes now and then in quiet contemplation, free from the importunities of foreman or clerk of the works. What object lessons one obtains as one watches how the necessities of the plan control the masses which compose the picture for the eye; how this chimney seems a false note, or that window ruins the privacy of some garden nook, or how yonder little bay, which is a delightful feature inside, seems but a sad excrescence on the outside, and moreover brings into view things better left unseen. It is from melancholy observations like these that one departs a sadder and a wiser man, with a resolve to do better next time, and gradually one is able to store up a mass of experience and observation which instinctively guide the pencil in the future. No doubt you who live in London indulge yourselves in these object lessons, but we who live in the country can do it so much oftener; and while you are stifling in the Underground Railway or swaying in the open air on the top of an omnibus furnished with what are called by way of mockery “garden-seats,” we can call in *en route* for the office and take a quiet look round at the work.

It is true that we suffer some disadvantages. We cannot repeat ourselves too often; we have to be careful in what houses we use our last and grandest design for a chimneypiece, but then we generally know what people call upon other people, and whether they are likely to see the interior of each other's houses. We have to be careful, too, how we make mistakes. You happy persons who conduct vast practices from London in remote corners of the land can afford to make mistakes in some of the remoter corners. First of all, are you not “London architects?” and does not that term endow you with a skill and knowledge impressive to all but the immediate sufferers and their intimate friends? And, granted that the mistake is so egregious as to convince even the indifferent, and to close your prospects of further work in that particular corner, why the place is very remote, and many a day will elapse before the news spreads to any of your other centres of activity, so long as you keep out of the law courts. Not so with us in the country. Most of our eggs are in one basket, and to drop that means losing our market altogether.

Yet another difference—in the main wholesome to us “rustics,” as we have been termed by you Londoners. Not only are we in touch with our work while it is in progress, but we have to live with it for ever afterwards. You Londoners may go down into the country and deliver yourselves of an abortion and forget all about it, but for us—Day after day we see our work; and day after day, as we turn the corner, we writhe afresh at our failures, or buoy ourselves up with the hope that the world will endorse our own secret opinion about our successes. It is no good; we cannot get away from our work; no ingenuity in the choice of routes is of any avail; there the buildings are, and to get from one place to another they have to be passed. But if rightly regarded this is a wholesome discipline; and the casual remarks of a stranger, or the criticisms of a reliable architectural friend, may be profitably stored up, like the sunshine and the rain which go to make the fruit in due season.

Living with one's work is indeed a wholesome discipline, and one is often tempted to wish in the interests of art (though not perhaps of the artificers) that some of our painters and sculptors had to live with the works which they send to the Academy. If this be the case with regard to our brother artists, whose productions can, as a last resource, be removed from sight, how much more so is it with us architects, whose designs are part of the structure itself?

If we architects were more accustomed to live with our own conceptions, I imagine there would be fewer of those picturesque features which we are so ready to bestow upon our clients. There is no better corrective of the wayward fancy than to live in a house of one's own design, and to bring to the sharp practical test of daily use all one's little fads of plan and decoration—the ingle-nooks and serving-hatches, and pretty grates and lead-light windows and stone mullions and panelled walls, and the hundred-and-one things that involve responsibility. I would not be thought to condemn the matters mentioned by any means, but I say that to live with the creations of our own fancy sobers the judgment and steadies the hand. And, therefore, we dwellers in the country find ourselves subjected to a wholesome discipline in living amid our work.

But have you any idea of what it is to live amid your clients? To meet them on the tennis-ground and the golf-links; to see them in the club, and hear them speak at public

meetings; to work with them or against them in the innumerable schemes that fill the leisure of dwellers in country towns? Do you know what it is to oppose one at a local election, to buy your hat of another, and to send back to a third the joint of meat that he has not cut to your liking? To us our clients are ordinary human beings, with a hundred objects in life, not gifts of Providence endowed with the sole desire of having a house built. We generally know something of their character in relation to other matters than building, and are able from the outset to form an opinion as to their likes and dislikes.

Another peculiarity of a country practice, which has its whimsical aspect, is the chameleon-like character of the people one has to deal with. A builder to whom you issue instructions from day to day, which he disputes at his peril, will once a fortnight sit in judgment on your plans at the local board; a foreman-bricklayer at one job will be on the building committee of another; the carpenter who makes the round of the building with you in the morning will sit at your side in the evening as your colleague in a debating society. And these contrasts of relationship are not isolated incidents, but are of constant occurrence. And far from being strange or embarrassing, they engender a mutual knowledge and respect which are of very great assistance in getting work well done.

But it is not only to the town itself that our attention has to be confined. Many a journey has to be taken into the country. Not a scramble for an express train, a tedious journey, and then a drive through country of which we know nothing, nor even the points of the compass, or what places lie on our left or our right. No, but leisurely drives through country which we get to know better month by month, and with the chance of choosing a suitable day for the work. We see the same scenes under every condition, with the early or the late sun, or under the steady blaze of midday. Sometimes we see them in a clear and brilliant atmosphere, like that of Logic and Science, when the distant and the near seem equally easy of access. And then, again, we see them veiled in a delicate mist, which, like Poetry, lends distance and proportion. The valley that at one visit ripples as the breeze touches the silvery hay, at others will ripple, perhaps, with the broad waters of a flood, or lie shrouded in the monotonous mantle of the snow. At one time the way will be cheered by the bending bunches of the lilac; at another the road will take you near the delicate and delicious odours of a field of beans. Still later in the year the bright red admiral will flutter past and sun himself on the stones, while in the winter the attention is concentrated upon the course of action to be pursued if the horse should actually fulfil his frequent threats of slipping down. And so in our constant drives we get to know the landscape in all its moods, and every view becomes more valuable as our experience of its varying aspects increases.

I am induced to dwell thus on matters which are not actually architecture for two reasons, partly because I am anxious to convey to you some idea, if only a faint one, of the pleasures that attend a country practice, and partly because a constant observation of natural scenery has a very considerable effect on the temperament and tends to develop that habit of thought which helps us not only to satisfy the necessities of those for whom we design, but also to marshal the arrangements with which we endeavour to satisfy those necessities in such a manner as to express certain ideas, such as stateliness for the rich, and quiet unpretentious comfort for the well-to-do and homely, repose for quiet surroundings or aspiring vigour for hilly regions.

There is a very great deal to be said for giving a man a house suitable to his character, for adapting the design to his habits of life rather than inviting him to change his habits to suit your design. You may give him high-art fittings, and papers, and hall-floors and all such accessories; but there comes a time when your help is no longer required, when, in the natural course of things, you relinquish control over the building, and then, left to himself, he will be sure to sin grossly in respect of carpets, and furniture, and pictures, and knick-knacks and all the trumpery ornaments which the "stores" supply. And all this flood of barbaric splendour will submerge the features which sealed the triumph of your patience and rhetoric and sarcasm.

And there is a very great deal to be said for making buildings suitable to their locality. Tile-hung walls in London are as incongruous as a prim suburban villa in the open country. A villa in the country may be required of the same capacity and at the same cost as one near a large town, but assuredly it ought not to be of the same appearance. Half the charm of the best work arises from its spontaneity, and from the entire absence of any apparent effort. As you look at it you do not admire this or that feature as a *tour de force*, but rather regard it as inevitable under the circumstances.

But it is not only from nature that we can obtain delight as we drive in pursuit of a country practice. Very few are the villages that have not some relic of ancient days, upon which we can gaze with renewed pleasure at every visit; and not only

with renewed pleasure but with increasing knowledge. There is no building that I ever knew, no matter how intimately, from which it has not been possible to gather something fresh with every visit, particularly if accompanied by a friend of congenial pursuits. Different eyes look in such different ways that, even if no new feature is discovered, there is sure to be some new aspect to reckon with. And so these old friends have an ever-abiding interest. Like Cleopatra,

Age cannot wither them, nor custom stale
Their infinite variety.

And the advantage of a country practice is that these things come in our way in the pursuit of our ordinary vocation, without any special effort, and we get to know them as incidental to the general arrangement of things, and not as sacred objects of special pilgrimages.

But while some of the pleasure of a country practice proceeds from the scenes in which it is pursued, not a little of it arises from the variety of work which it entails. The interest never flags. Now it is a church, next week a school, perhaps in the town, or perhaps in a village. Before these are digested comes an infectious hospital or an infirmary. The scene may then change to a factory or a public-hall, which in its turn may be followed by a suite of offices, a shop front or some swimming-baths. A club, an hotel and a chapel extend the list, which is interspersed here and there with houses large and small. Not the least pleasant task is to deal with farm-buildings, where sights and sounds and smells are all eloquent of country life. The mind is therefore always occupied with endeavouring to become acquainted with fresh requirements. From the courtly parson to the bluff publican, or from the far-sighted manufacturer, careful of every penny, to the well-bred master of the hounds, whose chief desire is to have his house enlarged in strict harmony with the ancient portions—these are changes which any week, almost any day, may see. No doubt in London and other large towns you get some variety, but I cannot think that you, who are more or less specialists, can have such a wide and ever-shifting range as we who live in the country, and are compelled in the nature of things to take the work that falls in our way.

That is one of the governing factors of our life, that we must take what falls in our way, and so it comes that we "rustics" look on with some amusement at the controversies which shake you Londoners to the centre. "Architecture, a profession or an art?" What in the world does it matter which view people take? Let us do the work that comes to our hand with all our might, not waste our time on disputes of nomenclature. Do you suppose we who live in the country are going to set up some fanciful standard of kind—not of excellence, mind you—and tell our clients, "This is a factory, and therefore not architecture," or "That is a shop-front, that presents no scope for art, and therefore we are much obliged, but will you kindly go elsewhere?" Do you think we can afford to earn a reputation for eccentricity like that? Or do you suppose that it is any more possible for us to decline to survey some land, or give an opinion as to the price of building sites, or lay out a building estate when called upon to do so? Who is to do it if we do not? Architects who earn their living earn it through their clients obviously, and if they gain a reputation for wanting to make puzzling selections from the work that comes in their way, they may say good-bye to clients of all kinds, and where, then, will be the architecture pure and simple upon which they are to concentrate their cultivated intelligence?

A rich man might possibly afford to be eccentric, but under the conditions which govern country life I doubt whether even he would be anything but a negligible quantity. But the man who lives by his calling must, in the very nature of the case, satisfy the conditions which govern his calling in the place where it is pursued.

We may be told, as in fact we have been told, that this is all quite right, but it is incompatible with good architecture. "The proof of the pudding is in the eating." I do not believe it is incompatible where there is previous good training and enthusiasm for the work. That is what is wanted—enthusiasm, and a fixed determination to do the best possible: to face difficulties, to master the essential conditions, to acknowledge shortcomings frankly (at any rate to yourselves), and to resolve not to commit them in future. To spare no pains, either on the drawings or on the building, but to go at it again and again till you get the thing right.

It is here in this Association that I see "the hope of English architecture." Far from saying to you "Refuse surveying!" "Refuse to take out quantities or lay out estates!" I say, "Render yourselves competent to do these things. Do not imbibe the idea that from London only is good architecture to be bestowed upon England, but go out if you can into the fine free life of the country; carry into innumerable centres of activity the enthusiasm which you gain here by contact with other young and eager minds, so that the whole country may be leavened with the nobler aims, the greater culture, the more

refined taste which you acquire here." To do this effectually you must be ready to be a surveyor as well as an architect; but you have great names in the past to keep you company—John Thorpe and Inigo Jones and Christopher Wren. But if your names, like theirs, are to live, remember this, that though surveying is an essential part of your life duties, it is, after all, in your architecture alone that you can achieve immortality. Yet it is not given to all to live for ever on the tongues of men. How small is the number of ancient buildings that we can trace to their actual designers. And, after all, how small is the importance of a man's name in comparison with the quality of his work. And, therefore, if we dare not aspire to immortality, let us take comfort from this—that though our brows may never bear the fadeless laurel, nor Time inscribe us on the everlasting roll of Fame, no one can deprive us against our will of the consciousness of having done our work to the very best of our ability.

A discussion ensued in which Messrs. Pratt, F. W. Marks, Brodie, Greenop, A. C. Stockdale, Max Clarke, Walter Blackwell, Yates and Bolton took part. A vote of thanks, proposed by Mr. Pratt and seconded by Mr. Marks, was passed by acclamation to Mr. Gotch.

Bygones.

"Antiquity after a time has the grace of novelty."—HAZLITT.

THE DEDICATION OF CHURCHES.

THE subject of dedication may appear to relate to ceremonies rather than to building, but an essay by the late John Gage upon it contains so much curious information about churches it deserves to be recorded. In a communication to "The Travelled Thane, Athenian Aberdeen," he wrote:—

The dedication of churches had its beginning under the old law, and was observed by the holy Fathers in the new: whence the Synods both of St. Patrick and of Calcuith enjoined that no priest should offer up sacrifice in any church to be built, unless the bishop of the diocese first came and hallowed it.

Gregory the Great, in his instructions to St. Augustine, bade him not destroy the Pagan temples, but the idols within them; directing the precinct to be purified with holy water, altars to be raised, and sacred relics deposited; and because the English were accustomed to indulge in feasts to their gods, the prudent Pontiff ordained the day of dedication, or the day of the nativity of the Saint in whose honour the church should be dedicated, a festival, when the people might have an opportunity of assembling, as before, in green bowers round their favourite edifice, and enjoy something of former festivity. This was the origin of our country wakes, rush bearings and church ales.

That it was the early practice in the West, in imitation of the Eastern custom introduced by Constantine, to invite many prelates to assist at the dedication of a church, may be collected from the canons of the first Council of Orange, held in 441, and of the second and fourth Councils of Arles, held in 452 and 524; and among the English this solemnity was celebrated with the greatest pomp.

St. Wilfrid, Archbishop of York, having built a church at Ripon, of wrought stone, with columns and porticoes or aisles, had a solemn dedication, which was attended by Egfrid, king of Northumbria, and his brother Ælwin, with the abbats and ealdormen of the kingdom. The church was dedicated in honour of the Prince of the Apostles, and the Archbishop consecrated the altar, and having covered it with purple and gold, all the people came and received communion, and everything was canonically performed. From the altar Wilfrid enumerated the lands with which the church was endowed by consent of bishops and princes, and pointed out to the assembly the sacred places in different districts from which the British clergy had been driven by his countrymen. The kings feasted the people on the occasion for three days; and St. Wilfrid, for the good of his soul, presented to the church a copy of the Gospels written in gold on purple leaves, and cased with the purest gold and precious stones.

To the dedication of the church of Winchelcumbe, Kenulf, king of Mercia, brought with him Eadbert, the captive king of Kent; and there were present Cuthred, the titular king, thirteen bishops and ten ealdormen, beside an immense concourse of people. At the conclusion of the ceremony Kenulf led his captive to the altar, and as an act of clemency, granted him his freedom. This was followed by a royal distribution of presents, consisting of vessels of gold and silver, and garments, and the fleetest horses; to such as had no lands the king gave a pound of silver; to each priest a mark of gold; to every monk a shilling; and much was given to the people.

At Ramsey a conventual church had been founded by the ealdorman, or half king, Aylwin, in 969, under the direction

of St. Oswald, then Bishop of Worcester. It is described by the Monk of Ramsey to have been raised on a solid foundation, driven in by the battering-ram, and to have had two towers above the roof; the lesser was in front, at the west end; the greater, at the intersection of the four parts of the building, rested on four columns, connected together by arches carried from one to the other. The historian, who wrote after the coming into England of the Normans, remarks that the edifice was handsome enough for that mode of construction which was in use at that early time. In consequence, however, of a settlement in the centre tower, which threatened ruin to the rest of the building, it became necessary, shortly after the church was finished, to take down the whole and rebuild it. To the dedication of this second church at Ramsey, St. Oswald, who was become Metropolitan of York, invited all the thanes of the six neighbouring counties, and they were joined by Æscwin, bishop of the diocese, Æselm, Bishop of Dorchester, and the Abbots of Ely, St. Albans, Burgh, and Thorney. Before the ceremony began, all the assembly forming a ring, Aylwin, the founder of the church, from the midst of the people, read to them the charter of privileges granted to the monastery by King Edgar, and he conjured those present to gainsay, if they could, the title of the monks to their lands. As no one came forward, "I call then on you all," continued the ealdorman, "to bear witness before God that on this day we have offered justice to every adversary, and that no one has dared to dispute our right. Will you, after this, permit any new claim to be preferred against us?" Then, placing his right hand on a copy of the Gospels, Aylwin swore to defend the rights and privileges, as well of Ramsey as of other neighbouring churches which were named; after which his sons, and others in turn according to their rank, took the same oath, and, the book being laid on the altar, the abbots present received each of their defenders into the fraternity of their respective monasteries. The ceremony of dedication, which followed, lasted until a late hour of the day, and was closed with a solemn feast.

Wulstan, the monk, has left us a poem on the dedication of the cathedral church at Winchester, restored or rebuilt by St. Æthelwold. The dedication was honoured by the presence of King Ethelred and nine prelates, including the Archbishop St. Dunstan and the Diocesan St. Æthelwold. The description which the poet gives of the church and monastery is too long to be detailed here, but deserves the attention of the ecclesiastical antiquary; and such was the splendour of the dedication of this church that Wulstan says:—

*"Nunquam tanta fuit talisque dicatio templi
In tota Anglorum gente patrata reor;
Qualis erat Venta celebrata potenter in urbe
In Sancti Petri Cœnobio veteri."*

The last act of the reign of Edward the Confessor was a solemn festival proclaimed throughout the realm on the occasion of the dedication of the church at Westminster, and the king being on his death-bed at the time, the queen officiated for him, in the presence of all the nobles and bishops of the realm.

These examples of the pomp of the English in their church dedications will abundantly suffice, and the form of the ceremonial may be seen in their rituals. It appears from the pontifical which bears the name of Egbert, Archbishop of York, and the Missale Gellonense, that there was a particular form of notice or invitation given previously to a dedication; and the Church of England in her present order of consecration of churches preserves this custom, for the canons require that an intimation of the bishop's intention to consecrate the church, with the day and hour appointed for it, should be fixed on the church door at least three days before. We have also a verification of the acts of our Anglo-Saxon ancestors at the consecration of their churches in the present ecclesiastical canons of this country, which enjoin that the endowment and the evidence of the church to be consecrated should be laid before the bishop, or his chancellor, some time before the day appointed, in order to the preparing of the act or sentence of consecration against that day; that all things should be prepared for a communion, and the church be kept shut and empty till the bishop's coming, and till its being opened for his going in.

Perhaps one of the earliest forms of dedication which the Anglo-Saxon manuscripts afford is to be met with in a pontifical, now in the public library at Rouen, formerly belonging to the Abbey of Jumièges. According to this ritual the following order was observed.

The bishop in his pontificals, with the clergy, came at break of day to the porch of the church about to be dedicated, singing the antiphon, "Zaccheus, make haste, and come down;" and twelve candles being lighted and placed round the outside of the church, the litany commenced, which was chanted by the clergy and the people in alternate choirs as they moved thrice in solemn procession round the building.

Then one of the deacons going into the church, and shutting the door after him, while the rest remained without, the bishop going up to the door began the antiphon, "Lift up your gates,

O ye princes, and be ye lifted up, O eternal gates, and the King of Glory shall enter in." Whereupon all went in procession round the church, singing the twenty-fourth psalm, until they came again to the porch, when the bishop knocking at the door of the church thrice with his crozier, repeated the same antiphon. This ceremony was observed a second and a third time, the deacon within the church each time, as the bishop gave out the antiphon, "Lift up your gates," replying, "Who is the King of Glory?" After the third response the choir sung, "The Lord of Hosts, He is the King of Glory," and immediately the deacon opened the door.

The bishop now entered the church, crying, "Peace to this house and all who dwell in it; peace to those who enter, peace to those who go out;" and singing the eighty-seventh psalm, they proceeded up the church to the foot of the high altar, and lay prostrate on mats before it, while a short litany was chanted. At its conclusion they rose, and the bishop, with the end of his crozier, wrote two Roman alphabets on the floor, in the form of a cross, extending from the eastern to the western corners of the building.

Next came the blessing of water mixed with salt, ashes, wine and chrism, and the bishop putting some of the liquid upon lime, made mortar for closing up the relics to be deposited in the altar. This was followed by the purification of the different parts of the edifice and the precinct, which were severally sprinkled in order with the holy water.

The bishop, now standing in the middle of the church, dedicated it in formal words, and then sung the preface to the consecration, and going up to the altar proceeded to consecrate the altar stone, and afterward the walls of the church, anointing the same with chrism, in the form of a cross, in various parts.

Then the altar linen, vestments, corporal, paten, chalice, eucharistic vessels, censer, and other things necessary for divine service were brought in order by the sub-deacons and acolyths to be severally blessed; after which the bishop hallowed the cross, the bells and the font, and consecrated the cemetery.

They then went to the place where the people in prayer watched the relics which had been brought the night before for the occasion, and the litany being said, the clergy raising the shrine and singing canticles, carried it in full procession with crosses, censers, candlesticks, and many lights to the church. The shrine was placed upon the new altar, and the veil being drawn between the clergy and the people, the bishop with his own hand deposited, according to the Roman custom, the relics in the confessional or stone sepulchre of the altar, anointing the confessional with chrism; three particles of the eucharist and three grains of incense were then added and the whole closed up with mortar.

The bishop and clergy, now retiring to the sacristy, put on other vestments, and in the meantime the altar was dressed and the church adorned and lighted up and a solemn mass concluded the ceremony.

It may be added that it was the ancient practice for the bishop to deliver a discourse on the occasion, and the "Sermo de Dedicatione," beginning, "Natalem templi hujus," ascribed to St. Cæsarius of Arles, is to be found in another part of the pontifical of which we are now treating.

The length of the ceremony necessarily occupied many hours; and, unless the diocesan had been assisted by other bishops, it would have been impossible for him to perform the whole of it in one day. Bishops, therefore, came not merely as witnesses, but as coadjutors; and, where a variety of things were required to be consecrated, different offices were going on at the same time in various parts of the church.

The bringing of relics to a church about to be dedicated on the evening preceding the ceremony was the occasion of a vigil or wake; that is to say, the night was spent in watching, fasting and prayer. Chaucer uses wake in this sense:—

Aaron, that had the temple in governance,
And eke the other preestes everich on,
Into the temple whan they shulden gon
To praien for the peple, and do servise,
They nolden drinken in no maner wise
No drinke, which that might hem dronken make,
But ther in abstinence pray and wake,
Lest they that deiden—

The Sompnoures Tule.

Succeeding ages used the term wake to signify the feast which was annually kept to commemorate the dedication, on which occasion the young and old were wont to meet at break of day shouting "Holy wakes, holy wakes." The ecclesiastical laws of King Edgar are particularly directed to prevent excesses at these meetings, and to maintain the religious observance of them.

St. Ambrose, writing to his sister Marcellina on the occasion of the dedication of the new basilica at Milan, tells her, "Nam cum ego basilicam dedicassem, multi tamquam uno ore interpellare cœperunt dicentes: sicut Romanam basilicam dedices? respondi: faciam si martyrum reliquias invenero." Epist. xxii.);

whence it has been inferred that the deposition of relics at the dedication of a church was at first peculiar to the Roman ritual. This deposition of relics was prescribed to the English by Gregory the Great; and the usage of it, as well as the ancient Roman custom of enclosing in the altar with the relics three particles of the eucharist, is confirmed by the canons of the Council or Synod of Calcuith, held in 816.

In some instances scrolls were added, according to the directions in the Roman pontifical, intimating what relics were deposited, and to what saint the church was dedicated, and the name of the consecrator, and the year, month and day of the consecration: sometimes these scrolls contained the Decalogue, or a capitulary of the Gospels. It may also be observed that the National Council last noticed required every bishop dedicating a church to see that on the walls or altars of the church there should be painted the saint to whom they were respectively dedicated, a strong proof, if any were required, that there was no want among the Anglo-Saxons of native painters.

Gregory the Great, beside relics, also ordered hyssop to be used in our church dedications; and Bede relates, that St. John of Beverley having been sent for by Erle Puch, whose wife was dangerously ill at the time, to consecrate a church, miraculously healed the lady by means of some of the holy water that he sent her, which the saint had hallowed in the dedication of the church.

The ancient altar stone, known by the crosses graven in the centre and at the angles, is now frequently to be found in our churches, generally applied to sepulchral purposes. The crosses upon it were intended to mark the spots anointed with chrism; and, if I do not mistake, this was the object of the crosses once inlaid with metal, cut in the external walls of some churches, as in the cathedral of Salisbury and the churches of Edindon in Wilts, Cannington in Somersetshire, and Brent Pelham in Herts. It may also be observed that on one of the Norman pillars in New Shoreham Church are two Jerusalem crosses, probably graven on the occasion of the dedication.

Those who wish to understand the meaning of any of the mystical ceremonies, such as the lighting of the twelve candles, and placing them round the church, the writing of the alphabet by the bishop with his crozier, in ashes spread on the pavement, and the like, may consult a tract, *De Dedicatione Ecclesie*, ascribed to Remigius, Monk of Auxerre.

During the time the bishop was depositing the relics in the altar, the veil, out of reverence, was drawn, *extenso velo inter eos et populum*. The veil here spoken of was the curtain that anciently hung on the cancelli or lattice of the choir, and which was drawn during the more solemn parts of the service.

The author of the apostolic constitutions, perhaps the earliest ecclesiastical writer who describes the shape of a Christian church, tells us that it resembled not only a ship but a fold, "non solum navis, sed etiam mandræ habet ecclesia similitudinem;" and he explains its resemblance to a fold by showing that the clergy were separated from the laity, and that the laity themselves, according to sex, age and rank, had separate enclosures, under the care of different persons. From Eusebius we learn that the choir of the apostles, built by Constantine at Constantinople, was enclosed by a lattice of brass and gold, and that the choir of the church at Tyre was separated from the people by a lattice of wood beautifully wrought; and it appears from passages in St. Dyonisius, St. John Chrysostom, Theodoret and others, that there were curtains to the chancels. Lattices with curtains continue to be the custom of the Greek church; and though curtains have ceased to be used in the Latin church, Durand, Bishop of Mende in the latter years of the thirteenth century, says that in his time there was commonly a veil, or a wall, between the clergy and the people.

THE TRAINING OF INDUSTRIAL DESIGNERS.

TO the late Benjamin R. Haydon the credit must be attributed for being the first who in this century pointed out the necessity of a training of a high class for all who were concerned in industrial designs. The following paper, which he wrote half a century ago, it will be seen in many respects corresponds with the latest experience on the subject:—

Schools of Design.

In the Somerset House Drawing Book, No. 1, it is laid down:—1st. That ornamental art, as an imitative art, ranks midway between fine art and mechanical art, and partakes of the nature of both. 2nd. That the fine arts, in dealing with poetry, history and moral expression, occupy a ground in which the ornamentist has no right to enter. And yet, thirdly, that on beauty the artist and ornamentist occupy the same ground.

Again, the author says the power of imitating objects artistically is not adequate to the ends the ornamentist has in view, and yet at page 3 the author says, "It is not merely with lines the ornamentist has to do, he has often to represent the colour and effect of metallic substances, the glitter of gems, in short, to make a picture of the article manufactured, which shall

show its general character and appearance rather than the exact details of its form and ornament, and there is no other way of acquiring the power of doing this than by the habit of copying, as an artist, the objects themselves or similar ones."

Again he says, the ornamentist arrives at practice through science—the artist to science through practice.

And yet he says in the same page, "A saving of time would be effected, if the chief labour at commencement were bestowed (by the ornamentist) on drawing by the hand."

In reply to these inconsistencies I beg leave to state that—

1. The ornamentist and the artist both express their thoughts and inventions by the mechanical operation of imitating natural objects by form, colour, and light and shadow. Imitation of natural objects is, therefore, the basis of both ornamental art and high art, and the easiest plan of practising the eye to see, the brain to conclude, and the hand to obey, is the best plan at the beginning, both for ornamentist and artist.

A student may puzzle his memory so long by scientific distinctions, if he begin by science, as to find when he has acquired science his hand perfectly helpless; and therefore, both in the case of the ornamentist and artist, a certain degree of purblind practice of hand, eye and brain is absolutely necessary for the highest genius in each department, as well as the humblest, so that when their minds comprehend any principle of science, or any object of nature, their hands may at once be able to illustrate them by design.

No artist of the Greek and Italian schools was considered a great artist without science, and no ornamentist was considered a great ornamentist unless he was a great artist too. Raphael was a great ornamentist; Giovanni d'Udine and Cellini were artists as well as ornamentists, and the foundation of both characters is, first, a power of imitating what you see.

There is no doubt the imitation of senseless angles and cones and octagons and pentagons may generate a dead sort of mechanical imitation, but the mind of the mechanic and artist sleeps, because there is nothing whatever to interest their sensibilities in the progress. Give them beautiful eyes their sympathies are excited, and the circle and ellipsis being portions in the shape of eyes, they acquire the same power of imitation, and exercise their powers of thinking too; follow eyes by the nose; they learn the perpendicular; let them then practice the mouth; they are obliged to make it horizontal or at right angles with the perpendicular of the nose. The shape of the head is an ellipse, the forehead and chin portions of the circle.

A human head is thus got through, combined with a human look and a human expression. The students feel as they proceed. What practice for geometrical designs is left out in the figure? Then come action, repose, intention and thought by circles, ellipses, angles and perpendiculars, but combined as a whole to convey a meaning. When the artist and mechanic are got thus far show them, if you please, where is the geometry of the head and figure, practise them in angles and circles, that they may know their meaning; make them both men of science, if you like, and let the mechanic begin to branch off; but begin with making both skilful in hand, eye and brain by imitating the same object, for, according to our author at Somerset House, "a saving of time would then be engendered, if the chief labour at first were drawing by the hand."

If the power of imitation be the first power to be acquired, as I have proved, both from what I have said and what our opponent says, why separate the education of artist and mechanic? But what will you say, or he say, when he acknowledges that in the most important of all qualities of design, viz. beauty, the artist and mechanic stand on the same ground, and yet he would separate their education? And though he admits they stand on the same ground, yet he again says they proceed to exhibit beauty by a method totally the reverse to each other.

"Beauty," says he, "with the ornamentist is a quality separable from natural objects." I reply it cannot be. Beauty with the ornamentist, from whatever form taken and applied, excites the emotion in the work of the ornamentist, not because it is separated from the object to which it naturally belongs, but because to whatever object applied it has the power of again exciting the emotion, as it did when a component part of its natural object at first.

If a sculptor, says he, makes a lily, he models a lily. "Not so the ornamentist; the lily appears in his hands with a new individuality." Of course; but it is still a lily. The ornamentist makes it a cup, a vase; but I reply it is still a lily turned into a vase and cup, and if it be not like a lily, what would a sensible master say to a mechanic who showed him a cup made of a lily? "A lily! it is not a bit like a lily. Pray did you model a lily, or draw a lily?" "No, sir, I did not, because we ornamentists treat lilies with a new individuality." Very true, my pupil, but to be able to give a new individuality to a lily you must first be able to form a lily in clay, or by drawing; to model or draw a lily you must get a lily and study it; after studying it you must imitate it by modelling or drawing. Imitation is the foundation of all arts or design, whether

for the artist or ornamentist, and though the ornamentist turns a lily into a new office, if he cannot imitate a lily or a human figure, somebody else must be employed to do them for him, and this must prove to you, my pupil, the necessity of the ornamentist and the artist beginning alike. Because what applies to the lily will apply to the figure, and the arguments are as good in one case as the other, and both prove the same truth.

The author proceeds to say "that the ornamentist and the artist are imitators of nature, but in different senses—in the one the resemblance is fictitious, in the other a reality." I reply the resemblance in both is fictitious, and in both a reality, though the application is different.

The basis of all this sophistry is simply this: the London leading artists had been so accustomed to be by their rank, their payment, their honour, and their privilege, a distinct class, that they were shocked by any attempt to revive the old connection between artist and artisan. It was a sculptor, though rising from humble but respectable parents, who first intimated the insult of giving the artisan an education which would rank him more as an artist than, for 300 years, he had hitherto been in England, and, of course, without any imputation on the honourable motives of any one now; we all know there is a degree of sensibility as to duty, in defending the views of our superiors, if to them we owe our station and our existence in life—it is right it should be so, perhaps I do not know if one is not inclined to respect gratitude, if even it lead a man into the most egregious folly.

It is a question if the education of the mechanic be not of more importance than the great artist's. See how he worms himself into all the ramifications of domestic decoration, and consider, if he had, like the German and the Frenchman, the power of conveying his thoughts by drawing the figure, how prettily at a little cost the drawing-room of the middle-classes or their parlour or their bedroom might be made vehicles of history and poetry and design. The more the power of design is diffused the greater, and not the less, will be the employment of the great painters. The wealthy and the noble will always have the best of everything, and they who love the handsomest women, drink the best wines, ride the best horses, and claim the highest stations will not be very apt to desert the best artists when they want their efforts. I am decidedly of Burke's opinion. "Whatever turns attention to art, even the purchase of old pictures," said he, "reflects again on modern painters."

Never, I assure you, was British art in greater danger than now. This London school, by separating the artist and the mechanic and promulgating the doctrine that sound art and decorative art are distinct, will in all probability do more mischief than a century will remedy: because the facility of admission is great, young artists go to it, and all the horrors of gaudiness, glare, hardness and false taste will spread like wildfire amongst the rising generation.

What reason can be given that a flower should look in decoration like botanical preparations pasted flat on lime? Distinctness is necessary, of course, but why cannot imitations of nature be distinct without being inconsistent with the eternal principles of the great masters established by the greatest geniuses the world ever saw?

Titian, Velasquez, Rubens, Rembrandt and Reynolds made their imitations of nature on the basis of the philosophy of human sensations.

Equalities of effect distract: variety is necessary, but if carried too far pains. It is the same with every quality of imitation in the great works of the great masters, no individual requisite of imitating life is ever obtruded, whereas by the separation of the education of the artist and the mechanic, the imitations of the mechanic at present are all obtrusion and totally inconsistent with sound art. If a race of this offensive description issue out as designers for glass-paintings for rooms, for halls, what will the art be like in a few years? The combination of sound art can be seen to perfection in a glass window at Liverpool, where a fine picture has been copied with all the principles of imitation; it is a fine work of art in manufacture, and that is what should be the object in all schools of design.

Not long since, returning from Windsor, I went into the coffee-room of the Royal Hotel, at Slough, and found the paper on the walls full of pretty designs, from Faust (I believe). "Is this English?" said I. "English," said the waiter, with an air quite insufferable, "French, sir, of course!" Here is another case in point. Had the same principles of educating the mechanic been acted on at Lyons as in London, would this French artisan have been able so to please us in the middle class by such a display, and is not every visitor excited and improved by such a simple way of recalling the scenes of some beautiful poems?

I apologise for this long intrusion; my engagements preclude the possibility of continuing this important question, but I promise it shall not rest whilst I live, for I know its vast national importance, and that we have only to add mastery to design to our indisputable quality of material, to take the lead in the world.

In conclusion, I deny in toto that the mechanic has no

right to mingle history, poetry and moral expression in his manufacturing design; what right has any man or any body of men to fix a limit to the exercise of human ingenuity? The Almighty sometimes gifts a Byron, and sometimes a Burns, and reflects on the principles of our own noble aristocracy. Who more tenacious of their rights, but who more useful as a check on the Crown and the people? and who is refused admission into their class, even from the humblest amongst us, if genius, guided by conduct and decorum, prove any individual worthy to be a great lawyer, soldier, sailor or statesman? If it were not for this wise decision, what would have become of the aristocracy long ago? and with such an aristocracy in government, are we to establish one in art, where no genius, no decorum and no conduct will procure elevation and reward for the humble mechanic? Ridiculous—the bare thought and promulgation will make us the laughter of Europe, if this preface has not done so long since.

The artists must become workmen and the workmen more artists, before the great revolution, beginning will begin aright; but it will not be by putting forth theories which will separate them more and more than ever, but by being convinced, as the great continental schools have long been, that as imitation is the basis of both arts, the students in each should begin alike.

At the revival of art in Tuscany artists were artificers and artificers were artists in the strictest sense of the words. "It was not in the academy but in the workshop their genius was nurtured—the *arte degli orefici*." "The goldsmith's craft was the chiefest school; hence came the best artists of all the three arts of architecture, painting, sculpture—Brunelleschi, Ghiberti, Orcagna, Luca della Robbia, Massolino, Ghirlandaio, Pollajuolo, Botticelli, Verrochio, Francia, Finiguerra, Andrea del Sarto, Baccio Bandinelli, Cellini, Salviati, Lioni, Vasari, and a host of inferior names, all were brought up to this good trade. Painters were chiefly employed as decorators of houses and furniture, &c." In all the associations of artists, trunkmakers, varnishers, saddlers, cutlers and all workmen in wood or metal whose crafts had any connection with design were admitted; and yet in England they are to be separated in education.

I think, therefore, that there is nothing "very erroneous in saying that the power of imitating natural objects artistically ought to be the first requisite in the education of the ornamentist, or that the artistic imitation ought to begin by the human figure, since the mastery of this would render every other attainment comparatively easy."

To conclude, the error of the first council of the London School of Design was this, viz. adopting the German instead of the French principle in educating the mechanic. The French begin by the figure and sound art—and the artisan thus educated carries sound art to ornament. The Germans begin by ornament and make the figure and sound art the second step—and the Germans never recover the false taste of their education.

It is not yet too late to remedy this great mistake, by passing a law in the council that every mechanic, as at Lyons, should be obliged to begin by the figure; and if this be not passed, I predict a corruption of taste in artisan and artist which will throw the art into hideous confusion for years.

ARE FINAL CERTIFICATES BINDING ON CLIENTS?

THE case *Cunliffe v. Hampton Wick Local Board* came again before the Courts on Tuesday, when judgment was given in the Queen's Bench Division by Lord Coleridge and Lord Justice Lopes. According to the *Times* report, it was an action by a contractor against the board to recover an alleged balance on a contract to construct new sewers for the district, they counter-claiming for 900*l.* for the cost of reconstruction of a part of the sewers; and the official referee having found in favour of the board on that counter-claim, he now appealed against the referee's report. The contract, on August 14, 1889, was that, in consideration of the sum of 5,523*l.*, the contractor agreed with the local board to do the works in the construction of the main sewers, branch sewers, &c., in accordance with the specification and under the superintendence and to the satisfaction of the surveyor, and subject to certain conditions—(1) he was to provide everything requisite for the due execution of the works in the specification; (2) to conform to the regulations of the local authorities; (3) to amend any errors in the works on the requisition of the surveyor and on request to provide what is necessary and to provide all materials which may be necessary for the works, all materials and workmanship to be of the best possible kind; (6) the contractor not to vary or deviate from the specification or execute any extra work unless required by regulations or unless upon the authority of the surveyor by order in writing; (7) any authority given by the surveyor for any alteration or addition in the works is not to vitiate the contract, but, unless the price should be agreed upon, to be measured and valued and certified by the surveyor; (10) should any of the works be, in the opinion of the surveyor, "executed

with improper materials or defective workmanship the contractor is, when required by the surveyor during the progress of the works, forthwith to execute the same, and in case of default the surveyor to have power to employ other persons to do it, and the cost is to be borne by the contractor; (11) any defects and other faults which may appear within three months from the completion of the works, including any additional or extra works authorised by the surveyor under (6) and arising out of defective or improper materials or workmanship, are, on the direction of the surveyor, to be made good by the contractor at his own cost; (14) the works to be completed in six months from the commencement; (16) the contractor to be entitled to receive the balance of all moneys due to him at the expiration of the period of maintenance of the works, that is, three months from the completion of the works; (17) the certificate of the surveyor showing the final balance due to be conclusive evidence of the works having been completed. Such being the nature of the contract, it appeared that, though the land is very far below the level of the river—and the soil is wet and sandy and unstable—the specification did not in terms provide that the pipes should be laid on concrete, and, in fact, the contractor did not so lay them; and though it was required that there should be concrete at the "bends" or junctions, this, it appeared, according to the findings of the referee, was not fully carried out, and in the result many of the junctions gave way and pipes were broken. When the work was completed, disputes arose between the board and the contractor, which it was proposed to refer to arbitration. On April 6, 1891, however, the surveyor gave a certificate that the works under the contract and the extra works in connection with the same had been completed to his satisfaction, and that Mr. Cunliffe "was entitled to receive the balance of 637*l.*" But the board were dissatisfied with the work, and disapproved of the certificate being given, and, indeed, discharged the surveyor and appointed another. The contractor, however, relied on the certificate; and, in addition to this, the contractor made two claims for subsequent work, bringing the amount claimed to 747*l.* But in the meantime the new surveyor had required the contractor, under clause 10 of the conditions, to re-execute portions of the work. This clause related chiefly to the part of the sewers belonging to Vicarage Road, as to which the case stood thus:—The final certificate having been given on April 6, 1891, the three months given by the contract would expire on July 6. In June some stoppage was discovered, which led the surveyor to order part of the sewer to be taken up to discover the cause, which was found to be the breakage of a pipe, and he afterwards directed the whole of the Vicarage Road sewer to be opened up to discover any defects. The Vicarage Road portion was divided into three sections. The first was opened in July 1891, the second in September 1891, the third in December 1891. The surveyor then directed the whole of the Vicarage Road sewer to be taken up and re-laid with concrete and flagstones, on account of the wet and treacherous nature of the soil. In the meantime a new surveyor was appointed, and this new surveyor declared the work in the Vicarage Road and Hampton Wick Roads was badly done, and required it to be re-executed by the contractor under the 11th condition, on the ground that the work was badly done; and, on his refusal, had it done, and made a claim of 210*l.* for work done in making a good sewer in Hampton Wick Road, and 688*l.* for work done in making a good sewer in Vicarage Road. Further they claimed damages at the rate of 50*l.* a week from February 14, 1890, to April 6, 1891. The plaintiff disputed these demands, and the parties being thus at variance this action was brought on July 6, 1891, and in this action the board counter-claimed for nearly 4,000*l.*—that is, nearly 3,000*l.* for delay and 908*l.* for the cost of re-executing the works, &c. The case went to an official referee, whose first report was in October last, and a question arose as to the time from which the period of three months was to run, and the Divisional Court and Court of Appeal held that the three months were to be calculated from the date of the certificate of completion of the works, and sent back the report to him on that point, and in February last the referee made his report—that the plaintiff was entitled to recover 622*l.* 2*s.* 9*d.* on his claim; and that the board were entitled to recover from him 909*l.* 17*s.* 3*d.* on their counter claim; and so he directed judgment to be entered for them for 287*l.* 14*s.* 6*d.*, against which the contractor now appealed. The referee, in the course of the case, observed that, with reference to the nature of the soil, probably the original design was defective in not providing that the pipes should be laid in concrete, and he did not allow the board for the flagstones, as that was an improvement; but he thought that the contractor had not properly done what he was required to do as to the concrete at the junctions, and this was a defect—the cause of the mischief—for which the contractor was responsible, and that was the basis of his report.

Mr. Lankester, who (with Mr. A. Hudson) appeared for the contractor, contended that the report was wrong, and that the referee had misunderstood the contract. The eleventh condi-

tion only applied, he said, where the contractor had badly done the work, and the defects discovered had arisen from such bad work and the surveyor had overlooked it; but the surveyor under whose orders and direction he had done the work had not been called to show this, and the work, it must be presumed, was done under his orders.

Lord Coleridge, however, pointed out that by the express terms of the contract the work and materials were to be the best possible.

Lord Justice Lopes also pointed out that, according to this contention, if the surveyor passed over bad work it could not be complained of.

No; it must be admitted that the certificate is not conclusive. But then it must be proved that the work was badly done and the onus of proof is on the employers.

Lord Coleridge: The contractor is to do the work well, with the best workmanship and materials, quite independent of the approval of the surveyor.

It is subject to this that the surveyor did not approve it, but overlooked it.

Lord Justice Lopes: That view entirely destroys the condition.

It is manifest that the first surveyor had approved the work, for he gave his certificate, and he was not called to show that he had not approved or had overlooked the defects complained of. The truth is that the sewers were originally, under the sanction of the surveyor and with the knowledge of the board, or a cheap system unsuited to the "wet and treacherous nature of the soil," and the new surveyor had the sewer in question relaid on a proper, but more expensive, system, and then sought to charge the contractor with the expense, and the referee had charged the expense to the contractor, thus making him pay 900*l.* for re-executing this work in a better way. The referee, therefore, has decided on the wrong principle and on a wrong view of the contract, and his report should be set aside.

Mr. Horace Ivory appeared for the Board, and first submitted that the question was one of fact, on which the referee was in the position of a jury, and that so, his findings could not be set aside if there was any evidence on which he could so find. [The Court, however, dissented from this, and called upon him to support the findings of the referee.] He had found, as a fact, that there had been bad work in the Vicarage Road sewer. The question is not confined to the opinion of the surveyor at the time the work is done. [Lord Justice Lopes: Suppose he has died?] Just so, or has been removed. Now, as early as June 1891 the sewer was found to be stopped, and surely that was a defect which appeared within the three times. It was true that the cause, the breakage of the pipe, was not discovered until July. But the operation of taking up the sewers to discover the cause was necessarily continuous, and they had to be taken up until the cause was discovered, as it was, and it was found that there was not only one breakage, but that there was a breakage at every junction, so that there was a series of defects in the sewer which had caused the stoppage.

Lord Justice Lopes: And made it necessary to take up the whole of the sewer?

Just so.

Lord Justice Lopes: But might it not be said that these defects arose from a fault in the design?

It was said, it was urged before the referee; it was the main point taken before him, and he found that the concrete was improperly put in, and that this had caused the breakages at the junctions. The referee had found that the concrete was so put in as not to support the pipes. It was not a question of design, but of execution. It was urged that the contractor had carried out the orders he received from the surveyor. But that was not so, and the referee had expressly found the contrary. In fact clay had been put in instead of concrete, and the work was "scamped." That was the real cause of the mischief, and it was on that the referee found. The orders given were that at each "bend" or junction three barrels of concrete should be put in, whereas at most of them only a barrel and a half was put in, and the rest filled up with clay. That was the defect. It was true, as the referee said, there might be a defect in the design. But he expressly found that the mischief had not arisen from the design, but from defective material and workmanship. He had his mind directed to that very question, and he had expressly found upon it, and he had only allowed to the board the cost of remedying the defects which caused the mischief, and so he had not allowed the expense of the flagstones, as it was an improvement on the original design. The referee, therefore, was justified in his findings and in the report founded upon them.

Mr. Lankester was heard in reply. He urged that the contractor had a right to rely on the view taken by the surveyor who acted when the work was being done. [The Court, however, as before, rejected this view distinctly. Their Lordships pointed out that the contract in this as in other cases expressly provided that the contractor was to obey the directions of the surveyor "or any other surveyor" who might

be appointed. Lord Justice Lopes asked what was to be done if the surveyor first appointed died, or became incapacitated by illness. Lord Coleridge said, Suppose the board thought their surveyor too easy, and playing into the hands of the contractor, and discharged him? Then great injustice may be done by the appointment of a new surveyor who takes too strict a view. [Lord Coleridge: That is provided for by the usual arbitration clause, which applies to any "dispute or difference."] Only one breakage was found within the three months.

Lord Coleridge: But that necessitated taking up the sewer, and then it was found that at nearly every junction there was a breakage.

Lord Justice Lopes: It was probable that these breakages had occurred before, and they were certainly faults.

At the close of the arguments, which, with a brief interruption, took up all day, their Lordships pronounced judgment in favour of the board.

Lord Coleridge said the court would have been ready to send back the case again to the referee if they thought, on the ample argument it had received, there was any ground for taking that course, quite certain that he would do justice to the parties. But they did not think that it was necessary to take that course. He had thought from the first there were defects in the execution of the works, though on the first reference, in his view of the effect of the contract, the three months had elapsed. That view having been corrected by the Court and the case having been sent back to him, he had found that to a great extent the mischief had arisen from a faulty execution of the work. It was true that he had observed that the original design was defective, but he had found that the mischief had arisen from its faulty execution. The proof of that was that there was a method by which the defects in the design might have been obviated, and in some few cases this method was directed and adopted, and in those cases no mischief had resulted. But in all other cases that method had not been adopted, and the mischief had resulted; the cause being that there was no firm and proper support for the pipes. It was urged, indeed, that a large portion of the sewer had been taken up and relaid, and that it was unfair to charge the contractor with that, as the stoppage was only at a particular place. But the leakage first discovered had led to a further examination of the sewer, and a great many junctions were found broken and were restored. Now, it was a question of fact; and there was evidence on both sides, and the question was for the surveyor to decide. It was objected that this was a new surveyor; but the contract provided expressly that the contractor should follow the directions of any surveyor appointed by the board, as otherwise, as had been pointed out, great absurdities would arise. On the whole, therefore, there was no ground for sending the report back to the referee, and the appeal against it must be rejected.

Lord Justice Lopes concurred. He quite agreed as to the construction of the contract; and there was evidence on which the referee might find, as he had done, that the mischief had arisen from defects in the execution of the work, and not from the design or from the direction of the surveyor.

Appeal accordingly dismissed.

DUNDEE INSTITUTE OF ARCHITECTURE.

AT the fourth ordinary meeting of the Dundee Institute of Architecture, Science and Art, Professor Steggall delivered a lecture on "The Influence of Town Life on National Character." He argued that the depopulation of the country districts and the increase of the number of dwellers in large cities tended to the loss of individuality, of patriotism, of independence, of reverence and of judgment, and that that fact affected the national character. The balance of opinion was averse to the theory that large towns were on the whole the best. Dealing with the health aspect of the question, he said that although the influence of health on national character was indirect its action was universal. On that point they had a serious case against large towns. In Glasgow 42,000 families out of 126,000, or one-fifth of the whole, lived in single rooms; in Dundee 1,000 families, from five to nine in number each, resided in one apartment; 7,500 other families of a less number than five also lived in a single room, the total being 8,500, or nearly one-fourth of the whole. In elaborating that point and alluding to the recreations of the citizens of large cities, Professor Steggall stated that of all the forms of exercise that had been introduced within the last twenty years the bicycle had been, and was likely to prove, the most beneficial to the health of the community. At the close the lecturer was accorded the thanks of the meeting. Lately attention was drawn to the fact that the Brechin Corporation had advertised for competitive plans for proposed municipal buildings. Remarks were made to the effect that such competitions were derogatory to the profession of architects, and it was resolved to send to the advertisers a copy of the rules of the Royal Institute on the subject, and

suggest that the Brechin Town Council should conform to these rules. At the last meeting it was stated that no action had been taken by Brechin.

EDINBURGH ARCHITECTURAL ASSOCIATION

ON Saturday, the 25th inst., members of the Edinburgh Architectural Association paid a visit to Glasgow, and were shown over the municipal buildings and the cathedral. Among the party were Messrs. W. W. Robertson, president; T. Fairbairn, hon. secretary; John M'Lachlan, Balfour Paul, Thomas Ross, James Kennedy, J. M. Gray, J. Bryce Mortimer, James Bruce, W.S.; Mitchell, W.S.; and Wallace R. E. James, S.S.C. On the arrival of the party at Queen Street Station shortly after two o'clock they were met by Mr. John Honeyman, architect, Glasgow, and at once proceeded to the new municipal chambers. The company were shown over the building by the custodian, Mr. M'Leod, and before leaving, on the motion of the President, a vote of thanks was awarded the Lord Provost and magistrates for their courtesy. The cathedral was next viewed, and Mr. John Honeyman pointed out its different styles of architecture. Subsequently some of the members of the party visited the new Barony Church, designed by Messrs. Burnetson & Campbell.

THE LATE J. S. CROWTHER.

THE death is announced of Mr. Joseph Stretch Crowther. In Manchester and the neighbourhood, says the *Manchester Guardian*, Mr. Crowther was, of course, best known as an ecclesiastical architect. His first work of any importance in this department was St. Mary's Church, Moss Lane, Hulme, built by Mr. Wilbraham Egerton, of Tatton, and consecrated by Bishop Price Lee in November 1858. This church is still regarded as one of the best specimens of Gothic architecture on the south side of Manchester. In 1874 he was commissioned to design the well-known church St. Alban's, Waterloo Road, Cheetham, and, at a subsequent period, during the rectorate of Canon Knox Little, the schools of the same church. In 1875 he designed the important new church of St. Mary's, Crumpsall, the original structure of which had been struck by lightning and burnt down. His next work of moment, and that which in point of importance ranks next to the restoration of the Manchester Cathedral, was the Bury parish church, which was rebuilt from his designs in 1876. This edifice was always regarded by Bishop Fraser as "the gem of the diocese." Another work of considerable importance was St. Benedict's, Ardwick, erected by the late Alderman J. Marsland Bennett, and consecrated by Bishop Fraser in March 1880. In 1885 he restored the chancel and other parts of the parish church of Rochdale, and in 1890 he designed the chancel for Littleborough parish church at a cost of 7,000*l*. As is well known, Mr. Crowther's principal work has been in connection with the Manchester Cathedral, the restoration of which he had fortunately completed just on the eve of his death. This restoration was commenced some ten years ago, and it may be said to be the crowning act of Mr. Crowther's busy and active life, not merely because it was his last, but because it is by far the most important undertaking on which he has been occupied. Mr. Crowther was a staunch Churchman; indeed, he was a High Churchman, and with his friend Mr. Edward Herford was a strong supporter of the Free and Open Church Movement at a period when it was less powerful than now.

ST. PATRICK'S CHURCH, SOHO.

A NEW church for Roman Catholics has been opened in London. The site is at the corner of Sutton Street and Soho Square. The style is Italian Renaissance. The church is built mainly in red brick. A campanile rises to the height of about 125 feet. The portico is of white Portland, supported by Corinthian columns and pilasters. The entrance porch leads through folding doors to the antechapel, or narthex, divided from the church by iron gates. This portion of the structure will remain open on all days. On the right is an entrance to the presbytery; on the left is a flight of stone steps leading to the tribune and sodality chapel. A few steps further a door leads down another flight of steps to a large confraternity room, which may be used for meetings, &c. Entering the church by the iron gates to the left is the baptistery. The organ is on the left of the sanctuary. The choir stalls are of carved walnut wood polished. The altar and altar rails are of choice Italian marble and richly carved. The sanctuary and altar steps are of marble, and the floor of the sanctuary of polished parquetry. On the left of the sanctuary is a small working sacristy, and on the right are the priests' and choir sacristies. On the right side of the church there will be five side chapels. The church consists of one open span of roof, and the floor space for benches is unbroken by pillars, so that a clear view of the sanctuary is

obtained from all parts. The lighting is from the clerestory. A semicircular roof springs from above the cornice over the windows. This roof is panelled and decorated. The new benches are of pitch-pine varnished.

The flooring of the church is in wood blocks, and the heating apparatus is of hot water. The total external length is 157 feet. The nave is internally 92 feet long and 34 feet wide, the total width of nave and aisles being internally 47 feet. The height of nave is 57 feet. The sanctuary is 27 feet long and 25 feet wide. The architect is Mr. John Kelly, of the firm of Kelly & Birchall, of Leeds. The contractor is Mr. W. H. Gaze, of Kingston-on-Thames. The wood-block flooring is by Messrs. Duffy & Co.

The Future of Architecture.

SIR,—Your own pages and those of other leading papers show very emphatically that there is much excitement in the architectural world just now, and it is to be hoped that it will not pass away without some permanent benefit to the noble art. The memorialists have spoken. The Institute has replied; but, if we may judge by the object of its general meeting of Monday last, it is not satisfied with its position. If this be true, should not a general meeting of architects be held to discuss the situation and appoint a committee, small but strong, representing both sides, or rather all sides, to report and advise as to necessary reforms; meeting again after adjournment for renewed discussion and final vote in a general meeting? One of two things must result from this course, either (1) that it is necessary to leave things alone, or (2) that certain changes at the Institute are imperative if the interest of architecture is acknowledged to be infinitely higher than the interest of the architect.

Who will be bold enough publicly to deny this proposition? —Yours obediently,
HERMES.

GENERAL.

The Eiffel Tower has been reopened and it is now possible on four days in each week to look from the open terrace on the fourth stage.

The Commission appointed to report on the designs for the Opéra Comique will be composed of MM. Jules Comte, president; Bardoux, Monis, Mesureur, Delaunay, Poubelle, Lozé, Sauton, Caron, Roujon, Régnier, Carvalho, Charles Garnier, Pascal, Moyaux, Daumet, Vaudremer, Caux, Aublé.

Mr. Reuben Bennett, of Manchester, has been successful in the competition for the decoration of the Huddersfield Town Hall. There were twenty competitors.

Mr. Joshua Horton, of Handsworth, has offered to give 1,000*l*. towards the restoration of St. James's Church, Handsworth, a work which will cost several thousands of pounds.

The "Bolton Chronicle" says:—Mr. A. Heaton Cooper has painted a picture of Wigan, showing the appearance of this ancient town in a realistic manner, and characteristic of the coal and iron industry. The picture is intended for the Royal Academy exhibition.

The New Reredos, designed by Mr. John Honeyman and executed by Mr. James Young, has just been erected in Glasgow.

Mr. J. P. Thomasson has offered a further gift of about 5,000*l*. to the Bolton Corporation, in aid of the Thomasson Park and Museum.

An Offer has been made to purchase and present to the Presbyterian College Committee a site of land on condition that a Presbyterian theological college be at some time erected on it. A further gift of 15,000*l*. would also be devised for the building of the college.

Mr. Temple Moore has prepared plans for the renovation of Redditch Church, at an estimated cost of 4,000*l*.

The Death was announced at Blackpool, on Tuesday, of Mr. Tuke, of the firm of Maxwell & Tuke, architects, Manchester. Mr. Tuke was at the time of his death engaged on the Eiffel Tower, Blackpool. Amongst other important works with which his name is connected are the Jubilee Exhibition in Manchester, the British section of the Brussels Exhibition, the Winter Gardens, Southport, and Cambridge Hall, Southport.

Mr. Edward Fitzgerald, architect, Youghal, died on Saturday, in his seventy-eighth year. He was also an enthusiastic archaeologist, and the credit of revealing the fine oak roof of St. Mary's, Youghal, belonged to him.

The Architect.

THE WEEK.

No less than one hundred and twenty-four sets of designs were sent in to the Salford Corporation in the competition for artisans' dwellings. A sub-committee of the Health Committee selected eight of the plans for further examination. The following awards are made:—Mr. WALTER SHARP, architect, Manchester, first premium, 50*l.*; Messrs. M'MURDO, HORNBLOWER & WALTERS, architects, London and Liverpool, second premium, 40*l.*; Messrs. MANGNALL & LITTLEWOODS, architects, Manchester, third premium, 30*l.* The first block will be erected in Queen Street, on land recently occupied by "dwellings unfit for human habitation," purchased by the Health Committee under their improvement scheme. The cost of the buildings is to be about 10,000*l.*, and the tenements will contain usually a living-room, bedroom, scullery, w.c., &c., forming a complete self-contained residence, suitable for workpeople living in so crowded a district.

THE conditions of the competition for the Opéra Comique, Paris, have been arranged by the committee. There will be only one contest. For the preparation of the designs two months are allowed. The first premium will be 10,000 francs, the second 6,000 francs, the third 4,000 francs, and there will be five supplementary premiums of 2,000 francs each. It will be necessary to submit three plans—a longitudinal section, a transverse section, and elevations of the principal and lateral façades. There will be an exhibition of all the designs during five days before the awards are given, and afterwards during three days. The competitors can elect five jurymen to act with those whose names were given last week. If the jury recommend the winner of the first prize as having competence to carry out the work, and if the details, estimates, &c., are approved by the Council of Civil Buildings, he will be entrusted with the commission by the Minister. The Builders' Union have petitioned the Minister in favour of the necessity of each design being accompanied by estimates from contractors who will assume responsibility for the figures.

It would be interesting to discover the percentage of the builders and contractors in Ireland who are in favour of a disturbance of the existing relations with England. It is only necessary to glance over the tables in the reports of the Irish Commissioners of Public Works to perceive how large is the sum expended on all kinds of constructive works, and which is advanced at a very low rate of interest. In a great many cases, especially arterial drainage, not more than a third or a fourth of the cost has been charged to districts or proprietors. It is not easy to perceive where an exchequer as generous and considerate is to be discovered, although it is gravely assumed the island will have to suffer from "a chronic plethora of money." The story which Mr. BALFOUR related on Tuesday reveals that the Irish people are not so carried away by enthusiasm as to forget how much turns on money, and how difficult it always is to obtain loans of money on terms that are not ruinous. "We lend Imperial money," said Mr. BALFOUR, "to build schools and glebe-houses in Ireland, and we lend it at 4 per cent. Well, an architect had sent in to a priest an estimate for a building, a glebe-house, I think it was. The priest said that the estimate was too high. The architect said, 'Take care; if the Land Bill passes there may be no British money at 4 per cent. to build glebe-houses.' 'Let us conclude the bargain at once, never mind the estimate,' was the reply." If opportunities were afforded the Irish architects, engineers, builders and contractors, and if they related their experiences of what Government money has done throughout the island, they would present the question under aspects that must make all parties reflect.

THE Panama fiasco does not appear to have made much of an impression on Parisians. They never were

more anxious to have Paris converted into a seaport by means of a costly deepening and alterations of the Seine. There are some reasons in favour of the project. Antwerp, which the great NAPOLEON endeavoured to ruin irretrievably, is yearly attracting trade which the Frenchmen consider should belong to them. Again there is a fascination in the thought of seeing big ships at Clichy in the vicinity of the city, which is irresistible to the Parisian mind. Besides the project, although costly, is not impracticable. The plan which gains most approval is by M. BOUQUET DE LA GRYE. It is estimated to cost 6,000,000*l.*, and as the works could be carried out in three years it is plain there are few engineering difficulties. The average depth of the canal need be only 6·20 mètres, and it is proposed to have a depth of 7 mètres. Although it would be necessary to have four locks, the distance between Havre and Paris may be traversed in seventeen hours.

It is satisfactory to learn that Mr. BALDWIN LATHAM is of opinion that landslips at Sandgate are not likely to be recurring phenomena. He has assured himself that the land included in the slip has become settled and will not probably move for a very considerable time to come, as the momentum with which it settled has caused an effective barrier to be raised on the seashore against its further settlement, and as at the time the ground was at its maximum degree of wetness every day there is less liability of any further movement. Mr. BALDWIN LATHAM sees no obstacle to putting every one of the houses at once into repair, without even waiting for the land-drainage to be completed, but he recommends the introduction of tie-rods wherever possible as security in case further settlements should arise. He also considers it very desirable that at as early a date as possible all the openings in the ground should be carefully filled in in such a way as to prevent any rain soaking into the cracks—that is to say, it would be well for the surface over these crevices to be raised somewhat, but it must be done with discretion, so as not to impede or allow water flowing over the surface to lie in proximity to the filled-in crevice. In that way the risk in the future will be diminished, as the ground cannot become as saturated as formerly. While there is a general desire to see Sandgate recover itself, nothing but the experience of years will persuade the public that it is a safe resort, and we are therefore afraid it will not offer so promising a field to the speculative builder as formerly.

THE announcement that Sir JOHN GILBERT, R.A., intends to present some of his paintings to the Corporation galleries in London, Liverpool and Manchester, is satisfactory for many reasons. In the first place, the gifts will be valuable, and of extreme importance as exemplifying one province of the art of our time. Sir JOHN GILBERT was the earliest to popularise the art of illustration in this country. The plates by CRUIKSHANK were limited in range, and as much might be said of the cuts by such artists as HARVEY, BROWNE, BUSS and others. Sir JOHN GILBERT presented the dramatic aspects of modern, mediæval, classical, biblical, or romantic subjects with equal happiness. As a book illustrator he was the foremost of our time. His water-colour drawings and oil-paintings bear some resemblance to his drawings on wood-blocks, because the one principle guided his hand. He never wished to suggest, like so many Academicians and other painters, that it was immense condescension on his part to co-operate in the production of woodcuts. If his figures were intended merely for a halfpenny tract they were sure to have character. Again, by presenting his work to municipalities, he recognises the truth that those bodies take more care to preserve paintings, and are more zealous for their appreciation than Government officials. It is well known that the policemen in the South Kensington Museum know more about the collections than the superior officials. It was Sir JOHN GILBERT's intention first to build a gallery for his pictures and make over the property to the nation. Afterwards he decided to enrich Liverpool and Manchester as well as London. There are fifteen or more oil-paintings, some of considerable size, in perfect and pure conditions, and all in handsome frames, and many water-colour pictures also framed.

PHILIPPE AND J. B. CHAMPAIGNE.*

THE name of PHILIPPE DE CHAMPAIGNE is likely to be remembered by visitors to our National Gallery while greater artists are forgotten: the oddness of his three views of the visage of Cardinal RICHELIEU always attracts attention. In the Salon Carré of the Louvre, his full-length figure of the Cardinal also exerts a strange power, as if RICHELIEU was still a dominating force in France from which art was not exempted. The artist was one of those men that are not easily classified. By some Frenchmen he is declared to be a representative of the French school. M. GAZIER, the author of the biography of CHAMPAIGNE which has appeared this week in Paris, declares that in his style he displayed more affinity with *POUSSIN*, *LESUEUR* and *LEBRUN* than with *RUBENS*; but there is no doubt that PHILIPPE DE CHAMPAIGNE, as well as his nephew *JEAN BAPTISTE*, were born in Brussels, although their family may have emigrated from Rheims. If Belgium has had the distinction of his birthplace, he found his training and patrons in France. When PHILIPPE arrived in Paris in 1621 (that is, in his nineteenth year), the French school of painting was still controlled by leading strings which were held in royal or ecclesiastical hands. There is no doubt he was not welcomed; there was apprehension that he might play the rôle of *RUBENS*. The young artist had been taught by *JEAN BOUILLON*, *MICHAEL DE BOURDEAUX* and one of *RUBENS*'s assistants, *JACQUES FOUQUIERES*. All through his life PHILIPPE was of a religious turn. His first dwelling was in one of the colleges that nestled round the hill of St. Geneviève; there he found another student who took a serious view of life and art, *NICHOLAS POUSSIN*, and who was at the time co-operating in the decoration of the new palace of the Luxembourg. The director of the work was *NICHOLAS DUCHESNE*, who apparently allowed his time to be monopolised by wall decoration, for we cannot recall a single easel picture by him in any of the French galleries. It used at one time to be repeated that the director was jealous of the talent and influence of his Belgian assistant, but that is one of those legends which do not rest on a stable foundation. PHILIPPE undoubtedly returned to his native city in 1627, and was occupied there when, in the following year, he received intelligence of the death of *DUCHESNE*, and an invitation from *MARIE DE MEDICIS* to assume the direction of the works. It suggests the position of painting at the time when we find that the correspondence between the Queen-Mother and the artist was conducted by an abbé. Towards the close of the year PHILIPPE married a daughter of his predecessor.

The Dervish in the Eastern fable excused himself for settling down uninvited in the Sultan's palace because it appeared to him to be a caravanserai. During the years that have elapsed since 1620, when *DESBROSSES* completed the noblest part of the palace, the Luxembourg has sheltered a great many tenants, who vanished as mysteriously as they appeared. With them the decorative paintings of which the Queen-Mother was so proud have also passed away. The great allegorical series which *RUBENS* devoted to her glorification is happily in the Louvre, retaining its pristine brilliancy, but the paintings which were executed by *DUCHESNE*, *PHILIPPE DE CHAMPAIGNE*, and the artists who co-operated with them, can no longer be identified. Still more strange is the fact that although at the time there was a great school of engraving in Paris, there seem to be no plates after the wall-paintings. Every record of a great work has passed away, like the glory of the *MEDICIS* or the justice of *LOUIS XIII.*

PHILIPPE DE CHAMPAIGNE in some way was able to hold on by the Luxembourg as an official painter, but research cannot trace his later any more than his earlier works. It was natural also that an official painter who had nothing of the Bohemian about him should be employed painting churches and chapels. These paintings also have disappeared, but we have always been of opinion that the

dramatic painting of a dome by *FLAMAËL* of Liège, in the church of the Carmes, bore some correspondence with *CHAMPAIGNE*'s paintings on the vault of that Carmelite convent which received *LA VALLIÈRE* when she fled from her royal lover. Two of his works of a decorative class, executed in 1634, remain. In the Musée of Caen is the painting executed for Notre Dame, Paris, the *Vœu of Louis XIII.*, and in Toulouse is one of the replicas of the *Cérémonie de l'Ordre de St. Esprit*. Amateurs have no reason to be grateful to the painter, for, according to *M. GAZIER*, he inaugurated that system of repetition which permits three or four collectors to possess the originals of one and the same *chef-d'œuvre*.

In the seventeenth century *CHAMPAIGNE* probably derived most respect because the *homme rouge* condescended to sit to him for portraits. *RICHELIEU* at first was not partial to *RUBENS* or to *PHILIPPE DE CHAMPAIGNE*. He was anxious that *MARIE DE MEDICIS* should entrust the commission for the scenes from the life of *HENRY IV.* to *ARPINO*, but when the Queen-Mother lost her power the Cardinal grew indifferent to the affair. *CHAMPAIGNE* painted the walls of his residences, but fate has not been more kind to those works than other efforts of the artist. In the Palais Cardinal—it is now known as the Palais Royal—where *RICHELIEU* died, *PHILIPPE DE CHAMPAIGNE* painted the vault of the gallery of illustrious men, that is, the twenty-five notabilities that *RICHELIEU* admired, the series closing with *LOUIS XIII.* and the Cardinal himself. The portraits of the Cardinal might be taken from a mask. He appears exceedingly quiet and unemotional, and might well be one of the clerks of the minister; he was not likely to wish the painter either to reveal or to flatter him in his features.

In painting the portraits of men of a different class *PHILIPPE DE CHAMPAIGNE* was not under restrictions and he could venture to express temperaments. While his portraits exist his fame will endure; the authorities of the Louvre were wise in securing so many examples. There is, in the first place, his own portrait, in which he suggests his birthplace by introducing its cathedral of St. Gudule and the tower of its Hôtel de Ville in the landscape that forms the background. On another canvas *FRANÇOIS MANSARD* and *CLAUDE PERRAULT*, the two architects, appear. It may be said that during a period of about forty years the majority of the great men of France sat to *PHILIPPE DE CHAMPAIGNE*. Many of the most interesting portraits are reproduced in *M. GAZIER*'s memoir. Here we have *TURENNE*, who, although not a Frenchman, and in spite of his Calvinism and foreign extraction, gained a marshal's bâton in his thirty-first year. In his last campaign, when he was sixty-four, he surpassed himself in audacity, although he was fighting in opposition to the desires of the king and his minister. The artist seems to have read his character more accurately than *BOSSUET*, *FLÉCHIER* or *MADAME DE SEVIGNÉ*, for while we are surprised to reconcile his cruelty with their eulogiums, it does not seem surprising that a man who looks so callous should devastate a province without any necessity. Then we have the portrait of Cardinal *DE RETZ*, which is a puzzle. Who could believe that this kindly-looking and commonplace man was a conspirator on a colossal scale, and at one time was indebted to the extent of four millions of francs? *MICHAEL LETELIER*, the chancellor, appears honest enough to deserve all the praise that *BOSSUET* bestowed on him. *VOITURE*, the poet, the first in France of the *bel esprit* type, appears as a simpering nonentity. We have, too, *JACQUES LEMERCIER*, the king's architect, who designed the Sorbonne, the Oratory and St. Roch—a face that is full of character.

There may be still one class of people in France who will set most value on the portraits, by *PHILIPPE DE CHAMPAIGNE*, which present to us the features of some of the men and women who were associated with the Jansenist experiment of Port Royal. The Abbé de St. CYRAN, who was a friend of *JANSENIUS*, came to Paris, and was able to persuade some ardent young theologians and some women of various ages to open two houses in which religious practices were to be followed. The *ARNAULD* family furnished some of the most enthusiastic recruits. *PHILIPPE DE CHAMPAIGNE* came under the new influence, and in many ways, as well as by painting, endeavoured to help the reformers. In the necrology of Port Royal it was recorded how he had always been most affectionate to the house,

* Les Artistes Célèbres : Philippe and Jean Baptiste Champaigne. Par A. Gazier. Paris : Allison et Cie.

how he had sustained its interests on all occasions even before grantees, and how he had bequeathed several pious pictures, as well as 6,000 livres. His daughter also became one of the nuns, and he has painted a portrait of her, accompanied by a nun, which is now in the Louvre. The artist was not afraid to depend for his effect on a large mass of one colour. In the full-length *Richelieu* of the Louvre the red gown is supreme, and in the portraits of the two nuns their creamy white robes are only relieved by blank walls and straw chairs. CHAMPAIGNE also painted a portrait of the superioress of the Convent ANGÉLIQUE ARNAULD. If we could believe in the doctrine of avatar, she might be taken as an illustration. Forty or fifty years ago she seemed to be a real person to some of the French academicians. COUSINS, MICHELETS, SAINTE-BEUVEs professed to have individually a property in the ancient nun. They appeared to know all her thoughts and to be in daily conversation with her; in consequence, the old gentlemen became deadly enemies of each other, for each claimed a monopoly and denounced his rivals as swindlers. The contest must have delayed the production of the famous dictionary, but it was amusing, for all the claimants to celestial communication were not remarkable for belief in supersensual affairs. One of the aims of Port Royal was to overthrow MONTAIGNE's "Essays," but it is a pity the old Gascon could not have a chance to say something in his homely, hearty style, about the ridiculous results which St. CYRAN's reform produced in our time. There was, perhaps, some excuse for the venerable immortals, as it is hard to study CHAMPAIGNE's portrait without having a misgiving that Mère ANGÉLIQUE had a little of the demure coquette under her robe. The nebulosity of her brother ANTOINE, who wrote 150 books which nobody dare read, is also suggested, and may well be contrasted with the head of St. CYRAN, that is as combative as BLUCHER's. The men of true succinct genius who were attracted to Port Royal, PIERRE NICOLÉ and PASCAL, were probably too engrossed with their work to become sitters.

The artist was so successful in portraiture there are many critics who believe that his Scripture pieces are often only groups of portraits. The figures are undoubtedly vigorous, and if PHILIPPE DE CHAMPAIGNE could be claimed as a native of Rheims, it is likely that more value would be attached to his Biblical scenes.

When PHILIPPE was in his twenty-ninth year his nephew JEAN-BAPTISTE, and to whom he showed a father's affection, was born in Brussels. He went through a similar course, worked at the painting of walls and ceilings in churches—indeed, his uncle would not allow him to accept commissions to depict lightly-clad Olympians, but there was no restriction to his representation of French victories, in which King LOUIS appeared as more than mortal. It is curious to discover that in those days the two CHAMPAIGNES were treated rather shabbily by COLBERT. The Minister was in his heart indifferent to all the fine arts, and merely used artists as tools to produce things that would gratify the royal vanity. Cunning is the characteristic of his countenance. He delayed payment for the painter's works; he employed architects to measure grand decorations and estimate their value by the square yard. Finally, he could boast of a victory, for PHILIPPE DE CHAMPAIGNE accepted cost price, which meant a saving of 3,000 francs to France. Can anyone wonder that Government departments in France should not have forgotten the precedent set by COLBERT, or that in England our officials exaggerate his methods?

Uncle and nephew appear to have led happier lives than most artists. Their style does not appear to have fallen into disrepute, for although the manner of LE BRUN was unquestionably more suitable to the costly and murderous pageants in which the king took part, the style of the CHAMPAIGNES was better adapted for buildings where religious functions were enacted. The younger artist evidently felt he did not possess the sort of genius that should assert itself, and he meekly allowed his co-operation to become almost unrecognisable. Fate has been in some respects hard on the pair, but some compensation is afforded by the genial biography of the artists which M. GAZIER has produced.

THE CLAIMS OF ARCHÆOLOGY.

AT the annual meeting of the Hawick Archæological Society a paper was read by Mr. J. C. Goodfellow on "The Status and Claims of Archæology." He alluded at the outset to the advance of this science within the last fifty years. Before that period the study of the remains of ancient nations was styled antiquarianism, and those who devoted their energies to it were looked upon as very little removed from the condition of lunacy. The antiquarian depicted by Scott was, though somewhat exaggerated, the recognised type of those who sought to add to their store of relics or to increase their knowledge of their predecessors in the drama of life. The study of antiquities had not progressed beyond the historical age. The antiquities of Egypt, Assyria, Greece and Rome had received attention from specialists and from contemporary writers, but before antiquarianism had treated on the life of the lower classes of the people there were almost no correct ideas as to how the masses lived, history generally taking cognisance only of the wealthy and powerful classes. The British Archæological Association was founded in December 1843, and since then had held a meeting annually, at which the president delivered an address full of information regarding the results of researches into subjects connected with the aims of the Association. The Archæological Institute of Great Britain was formed in 1845, and since then similar societies have been instituted in numerous towns throughout the United Kingdom. During the last six years the Rhind Lectures delivered in Edinburgh have done a great deal to indoctrinate the public mind in archæology. From the quantity (though small) of human remains found in the more northern tumuli it has been inferred that the northern tribes of England were occasionally compelled to become cannibals. Nor were the early dwellers in Scotland entirely free from being suspected of a like method of sustaining life when other classes of food were scarce. A good deal of information has been elicited concerning our rude forefathers. The cave-men who dwelt in crannogs and the earth-men who inhabited caves of natural formation, gradually became impressed with the necessity of having proper means of shelter, and in some cases of concealment. Hence it might be inferred that the construction of what John Hill Burton called "a very abundant class of structures" by the more recent dwellers in Scotland of the semi-savage type, who lived even before the race that inhabited Scotland when the Romans first visited these shores, showed a considerable advance in the life of these tribes. These earth-houses, cave-houses or weems, appeared to be scattered all over Scotland. Mr. David Macritchie has in "Underground Life" given particulars of over fifty of this class of dwellings, two of them on the Borders—at Newstead, Roxburghshire, and at Broomhouse, Edrom, Berwickshire. The passages of these underground houses are in some parts exceedingly narrow in breadth and low in height, being sometimes not more than 18 inches high and 2 feet wide. It has therefore been almost accepted as a matter of fact that those who constructed them were a diminutive race which has now completely passed away. That the underground dwellers were the predecessors of the brave and warlike tribes who, under King Galgacus, tried to resist the legions of Rome under Julius Agricola, the writer thought there could be no doubt. It has been asserted by some authors that underground dwellings were occupied until about 200 years ago. None, however, has inferred that those who first built them for shelter or retreat had occupied them since long before the Roman invasion. Mr. Goodfellow next glanced at ancient nations whose history had in many cases been supposed to be legendary. In Egypt there are memorials of a very ancient form of civilisation. The chronicles of Manetho, who stated that the ruling kings of Egypt had been composed of twenty-six dynasties before the country was annexed by the Persians under Cambyses the son of Cyrus, were for a long time considered to be mythical; but comparatively recent investigations had established the accuracy of Manetho's chronology, and the student of history now turns to the investigation of Egyptian antiquities, finding in them the memorials of a civilisation co-existent with the dawn of the historical era. Assyrian explorers had thrown an immense amount of light on the past state of nations which existed even before the great Assyrian and Babylonian monarchies which were contemporaneous with the Egyptian kings who erected the cities of Thebes and Memphis. It has been surmised that the Accadian nation must have been extinguished by the irruptive forces of barbarians who swept down with relentless force on a settled and industrious community, even as in later times the vast and imposing civilisation of Rome was submerged beneath the resistless onslaught of northern barbarians whose vandalic forces threw the consideration of art, literature and science into disorder and desuetude. Having adverted to the labours of Professor Nilsson, of Copenhagen, and our own Professor Wilson and other archæologists, Mr. Goodfellow glanced at the position now occupied by the Hawick Archæological Society. It was nearly 37 years since it was founded. Many of the original

promoters had departed to the silent land. He had on a former occasion (March 12, 1891) referred to his recollections of some of the more prominent of those whose enthusiasm and energy in antiquarian research led to the formation of this Society. If any names deserved to be inscribed on the roll-call of those who planned and worked for this Society, they were those of Robert and Alexander Michie and William Norman Kennedy. In a lesser degree there were others; but were he to name all those worthy of being so honoured he feared the list would tire their patience. Suffice it to say that the members had been able to do some small quantity of work which had enabled their town to stand forth in archaeological status, as in many other respects, "the Queen o' a' the Border." Their labours had been labours of love. During the 36½ years of the Society's existence nearly 200 essays, papers and lectures had been read at its meetings. They could rank among those who had honoured them with lectures and papers, the late Robert Young, minister of Teviothead; the late Rev. David Aitkin, D.D., formerly of Minto; the late David Dundas Scott, the learned translator of D'Aubigne's "History of the Reformation"; the late Professor Elliot, of Goldielands; Professor James Clark, a worthy son of "Auld Hawick"; Mr. Mark N. Robson; James A. H. Murray, LL.D., now of Oxford. Among the less learned, though not less worthy of recognition, might be named Robert Michie, Alexander Michie, William Norman Kennedy, Robert Murray, now of Galt, Ontario; the late Alexander Anderson Hogg, and the late Frank Hogg. The papers embraced a wide range. In the early years of the Society's existence the flora of the district received much attention from James A. H. Murray. Mr. W. Norman Kennedy's special department seemed to be the collecting of out-of-the-way anecdotes about notable persons rather inclining to wastral description, whom he with rare ability depicted under the heading of "Local Ethnology." Mr. Robert Murray chased the fairies and the gipsies, and depicted old local manners and customs; while Mr. Robert Mickie held fast to hill-forts, Roman camps, querns and nick-nackets of like character. The proceedings of the Society were printed annually from 1863 to 1885. These reports contain a mass of very valuable information relating to the town and neighbourhood—historical, biographical, critical and legendary. Nor were the reports of merely local value, for he recently saw in the catalogue of an Edinburgh second-hand bookseller one year's reports priced at 7s. 6d. About two years ago the Society published in a well-got-up volume its transactions for 1889 and 1890. Mr. Goodfellow closed by referring to works by Mr. Macritchie and Sir John Lubbock. He regretted that in these days the newspaper was more read than the treatise on past life and history, for those who comprehended the past were able to understand the present, and in some degree forecast the future.

THE INSTITUTE OF ARCHITECTS.

THE following correspondence in connection with the case *Burr v. Ridout* has passed between Lord Chief Justice Coleridge and Mr. J. Macvicar Anderson, president of the Royal Institute of British Architects:—

The President to Lord Coleridge.

March 11, 1893.

My Lord,—The attention of the Council of the Royal Institute of British Architects has been directed to your lordship's remarks addressed to the jury in the case of *Burr v. Ridout*, in which, referring to the schedule of professional practice and charges of architects published by this Institute, your lordship is reported in the *Times* of the 22nd ult. to have said that you "would not allow the Institute to dictate to juries what sum was to be paid for work not done," and again, "it was a most unjustifiable attempt by a body of men for their own advantage and to increase their own emolument."

With great reluctance I am obliged to take exception to these statements, because, were they to pass unnoticed, it would naturally be inferred that their justice is admitted.

To dictate to juries is a grave offence, of which I need scarcely say this Institute is innocent alike in thought and deed. Far from desiring to dictate to others, we do not dictate even to our own members.

The Institute publishes a schedule of professional practice and charges, a copy of which I enclose, which is not in any sense a code of imposed rules, but simply the embodiment in a convenient form of the general practice which usage has sanctioned. The charges referred to in this schedule are not binding or, to use your lordship's expression, "settled," in the sense of being obligatory. An architect is at liberty to charge what he deems his services to be worth by agreement with his client. Clause 9 of the schedule was never intended to justify, and does not appear to me to justify, such an imaginary case as that by means of which your lordship illustrated its supposed application. It necessarily assumes that the architect has performed the work entrusted to him in reasonable compliance

with the limitations imposed upon him by his client, and mutually agreed to with regard to expenditure.

It is to be regretted that learned counsel misinterpret the schedule by constantly referring to its clauses as "the rules of the Institute of Architects." The Institute has no such rules. The aim of the Royal Charter under which it is incorporated is not to impose arbitrary restrictions, but to promote the interests of architecture.

It is no doubt attributable to such erroneous interpretation on the part of counsel that your lordship was led to make the remarks I have referred to, and I feel sure you will be glad of the opportunity of relieving an honourable body of men from reflections which, if true, could not fail—emanating from so high an authority—to be prejudicial to the high character which it should be the ambition of every architect to maintain, and which it is the leading aim and object of the Royal Institute of British Architects to promote.—I have the honour to be, my lord, your lordship's most obedient servant,

J. MACVICAR ANDERSON, President.

Lord Coleridge to the President.

1 Sussex Square, W.

Sir,—I have the honour to acknowledge the receipt of your letter of March 11 containing your observations upon some remarks of mine in the course of my summing-up to the jury who with me tried the case of *Burr v. Ridout*, and which I understand you to have copied from a report of that summing-up given in the *Times* newspaper of February 22. I have no note of what I said, but I dare say my remarks are reported with substantial accuracy. I certainly have long and strongly entertained, and do entertain, the opinions and feelings therein expressed. They were not expressed in any exercise of a supposed judicial privilege to deliver oracular opinions on matters irrelevant to the issue, but they were necessary, as I think, to be expressed for the proper legal conduct of the case, and are to be justified by such necessity. The only words which, if I ever used them, I regret are "for their own advantage and to increase their own emolument." These words seem to impute a motive, and so far as they do I regret them. I have no right to confound the consequences of a rule, though very plain, with the motives of those who passed it.

Further than this I am unable to go. With the terms of contracts, however absurd and unjust they may appear, when both parties to them are free and know what they are about, I think it unwise and improper to interfere. But to justify the addition of preposterous terms to a contract on the ground of rules made by a body to which one of the contracting parties belongs and the other does not, and of which the last-mentioned party has never heard, is a very different matter. So far as any authority and influence of mine extends it never shall be done. I am obliged occasionally to say this in public in consequence of counsel, as you yourself state, endeavouring to justify charges utterly indefensible by citing the rules of the Institute in their defence. Where there is no specific sum for payment agreed upon the law implies a contract to pay what is reasonable, and what is reasonable is for the jury, not for the Institute of Architects.

I cannot help, before I conclude, mentioning as an illustration of the use to which the "Scale of Charges" is sometimes put a matter which came to my own knowledge. Many years ago a great nobleman employed an architect of great eminence to give him designs and estimates for a great work of restoration and almost rebuilding which he desired to undertake. The architect made designs and gave estimates. These were so very large that the nobleman gave up the work as far beyond what he could afford. He purchased the drawings, paid the architect several hundred pounds for his trouble and gave the matter up. More than ten years afterwards he had recourse to another architect, and executed under his control an entirely different building for less than half the money estimated by the first architect. When the work was completed the first architect demanded 2½ per cent. upon the nobleman's outlay, and justified this demand by the "Scale of Charges" of the Institute. I was consulted by the nobleman, and I advised that the claim was an extortion and that the nobleman should decline to pay one penny. The nobleman took my advice, and the architect's demand was not further prosecuted. This is by no means a solitary, though perhaps the worst, instance within my own knowledge of the manner in which some architects, and architects of eminence, use the "Scale of Charges" of the Institute, and I must claim the right to speak of such conduct as I think it deserves when the duty appears to me to be cast upon me of speaking at all.

I should be very sorry to be supposed to reflect upon the honour of a profession to which Michel Angelo and Sir Christopher Wren belonged. I am bound to respect their honour as much as I do my own, and I hope I have never been found wanting in this part of my duty.—I am, sir, your obedient humble servant,

COLERIDGE.

P.S.—Let me add that I have hardly expressed adequately my sense of the perfect courtesy and good feeling with which

you have discharged what must have been to you an unpleasant task, and I beg of you to accept my hearty acknowledgments.

C.

The President to Lord Coleridge.

March 20, 1893.

My Lord,—I beg leave to acknowledge your lordship's letter, and to express my obligation for the courtesy with which you have so promptly and fully replied to the remarks I reluctantly felt it my duty to address to you on behalf of the Royal Institute of British Architects. I have no reason to regret having done so, inasmuch as I have thus been so fortunate as to have elicited from your lordship a frank expression of regret—which I much appreciate—for having used words which seemed to impute an unworthy motive to the Royal Institute.

If I might refer to the opinion to which your lordship has given forcible expression respecting the use that is sometimes made of the Schedule of Professional Charges published by the Royal Institute, I would say with confidence that, although the Schedule may not be perfect in point of phraseology, it was certainly never intended to be used as a lever for claiming extortionate charges, and that such use, if resorted to, is perfectly unjustifiable.

In respect to the case which your lordship has quoted by way of illustration, the only surprise I experience is how any amount of ingenuity could extract from the schedule of the Royal Institute any justification for raising a new claim more than ten years after a settlement had, as I understand, been arrived at by mutual agreement.

The remarks to which I took the liberty to direct your lordship's attention have created a great deal of soreness among members of my profession, and I feel sure that it would be the source of much satisfaction were this correspondence to be published in the *Journal* of Proceedings of the Royal Institute. I venture, therefore, to express the hope that I may be favoured with your lordship's sanction to such publication in the next number of the *Journal*.—I have the honour to be, my lord, your lordship's most obedient servant,

J. MACVICAR ANDERSON, President.

Lord Coleridge to the President.

March 22, 1893.

Sir,—In reply to your letter of March 20 I am directed by the Lord Chief Justice of England to say that his lordship has no objection to your publishing the correspondence which has recently passed between him and yourself relative to the case of *Burr v. Ridout* and his lordship's remarks thereon.—I am, your obedient servant,

EGERTON B. LAWFORD, Secretary.

THE BATEMAN HEIRLOOMS.

IT has been decided to dispose of the Bateman heirlooms, and, in accordance with the order of the Court of Chancery, the first portion will be offered by Messrs. Sotheby, Wilkinson & Hodge on the 14th inst. This collection (which was begun many years since by the late Mr. T. Bateman, and afterwards considerably augmented by his son, the late Mr. W. Bateman, the author of "Ten Years' Diggings," &c.), embraces an extensive variety of objects. Amongst the enamels are a fine triptych of early Limoges in its original oaken case, and a charming little cup of later date, with figure of Orpheus, from the Bernal collection. There is also a very remarkable relief, exquisitely carved in Oriental alabaster, heightened with gold, of the Crucifixion, from the Earl of Shrewsbury's collection. The early ivory carvings are particularly noticeable, and begin with a remarkable diptych of the sixth or seventh century; but the gem of this series is undoubtedly the diptych, or, as suggested, covers of the Gospels, formed of two panels of ivory, depicting incidents in the life of the Saviour, mounted in a border of bronze gilt plaques, with figures in high relief, *repoussé*. This valuable example of early Christian art, originally from the cathedral at Trèves, was acquired in 1856 at the sale of the collection of the poet Samuel Rogers. There are also some very interesting specimens of early ecclesiastical art in metal, &c., such as reliquaries, chalices, and the head of a pastoral staff. Also amongst the later works in metal are two remarkably fine bronze ewers in the form of lions; and an exquisitely designed gorget of bronze richly gilt and *repoussé*, with a battle scene. The silver includes, among other specimens, a fine cup with cover of Nuremberg work, and a very interesting specimen of the silver-worker's art of the seventeenth century in the form of a mace, given by Charles I. to the Corporation of Leicester. An object that will doubtless attract considerable attention is an English hornbook of the time of Charles I., one of the very few specimens of its kind known. Messrs. Sotheby, Wilkinson & Hodge have published a catalogue with illustrations by the autotype process. The library and collection of coins will also be sold by Messrs. Sotheby during the season.

ANTONIO CANOVA.

IT was at Possagno, a little village situated amidst the Asolani Hills, at the foot of the Venetian Alps, that Antonio Canova was born on November 1, 1757. Though "science frowned not on his humble birth," a mud-wall cottage was his earliest receptacle. Pietro, his father, died when the boy was no more than three years old, and his mother, Angela Zardo, married shortly afterwards, and returned to Crespano, her native town, leaving her son to the care of his paternal aunt, and of his grandfather, Pasino. Antonio was thus left an orphan in his most tender years, and possessing but a feeble constitution and weak frame he required all the indulgent attention of his sympathising guardians. Caterina Ceccato, his aunt, nursed him with all the fondness of a mother, and infused into his heart the love of poetry by singing to him the wild ballads of his native country. The effect thus produced upon the flexible mind of the artist in relation to his future character may be inferred from his own warm acknowledgments of the melody communicated to his soul by those early strains.

His grandfather was no less watchful over his education in the line of art of which he was afterwards to be the greatest ornament in modern times. Though humble in circumstances, both the father and the grandfather of Antonio were sculptors of excellence in their way, but their operations were confined to the monuments, altars and similar works consecrated to the purposes of religion in the churches of their neighbourhood. His grandfather taught him the early use of the implements of sculpture, by which means he acquired that mechanical skill which has characterised his future works, and given to them a finish superior to that of any other sculptor.

The patrician Giovanni Falier has the merit of being the first patron of the artist. He introduced him to Giuseppe Bernardi, surnamed Torretto, nephew and pupil of Torretto, a Venetian sculptor, then engaged on some works in the neighbourhood of the villa of Asolo. It was in the tenth year of his age that Canova obtained the notice of the noble family of the Falieri, and the incident by which the young artist achieved that advantage is no less creditable to his ingenuity than his fortune was propitious in obtaining so excellent an opportunity for the display of his dawning talents. The youth had acquired a taste in modelling flowers, and at a feast prepared by the Falieri at their palace in the neighbourhood of the artist's birthplace a crowning ornament was wanting to complete the beauty of the dessert. Old Pasino had tried in vain to invent something for the occasion; the dinner was set forth, the guests were assembled, and the domestics were in confusion when young Antonio, with wonderful rapidity, modelled a lion from butter. Such was the skill with which this juvenile performance was effected that it excited universal astonishment among the assembly, before whom he was called, blushing, to receive their first applause and caresses, and to obtain the earnest of the distinguished patronage of the Falieri. The encouragement afforded by this small instance no doubt operated powerfully on the mind of Canova; from this period his fortune was made, and he was soon destined to receive the support of all the great and wealthy personages of his native land.

The young artist was placed with Torretto, and accompanied him to Venice, after the completion of the works which that sculptor had then in hand. The death of Torretto happening soon afterwards, deprived Canova of many of the advantages anticipated, and he was left without restraint to pursue his own course, when he had acquired little more than the rudiments of his art. Falier, his patron, still continued to protect him, and the source of knowledge in the gallery of plaster casts of the Commendatore Farsetti, in conjunction with the emulation excited among young artists at that time in the Academy at Venice, had a tendency to improve the taste of students precursory of future excellence. Canova was now placed with Gio Ferrari for about a year, after which, feeling convinced of the necessity of a wide deviation from the then rules of art, he determined on exploring new paths of study. His proficiency even at this period, when not more than fourteen years of age, is testified by two baskets of fruit, which are deposited on the first landing-place of the Farsetti palace, now the Hotel della Gran Bretagna at Venice.

In his sixteenth year Canova completed his first effort in following the tendency of his own genius. It was the statue of *Eurydice*, and in the following year he began that of *Orpheus*. But the most elaborate of his compositions previously to his departure from Venice was the group of *Dadalus and Icarus*, in which he is stated to have evinced his daring abandonment of conventional modes, and his devotion to the dictates of nature.

The strong manifestations of genius already given and the rapid progress made by Antonio induced his noble patron to procure for him an extension of means and a loftier theatre for the exercise of his powers, and, in concert with the Chevalier Girolamo Zulian, then the Venetian ambassador to the Holy See, Falier procured for the young artist the means of visiting Rome. Accordingly in December 1780 Canova entered for the first time that seat of the arts, and in the December following

the Venetian Government granted him an allowance of 300 ducats per annum for three years for his support during his studies. He now possessed the advantage of access to the house of the Venetian ambassador, which was indeed a kind of athenæum and frequented by all the genius and talent of the city. This enlightened and accomplished nobleman, entertaining a high regard for the genius of the youthful artist, procured from Venice a plaster group of *Dædalus and Icarus* for the purpose of exhibiting it to the artists and connoisseurs at Rome. The group was shown in the presence of Canova, surrounded by Cades, Volpato, Battoni, Gavin Hamilton, Puccini and others, who viewed it with silent astonishment, not daring to express censure at the variance of style from the established rules. Canova has frequently expressed the embarrassment and anxiety he felt on this occasion.

On his arrival at Rome Canova commenced a critical study of the best models of ancient art, but not with any view of sacrificing his previous regard for nature. He still preserved his contempt for conventional modes in the arts and blended the most lofty conceptions with correct taste. It must, however, be admitted that the auspicious circumstances by which he was surrounded materially contributed to awaken those sentiments in his still youthful mind. And to give him credit for an intuitive perception of all those great principles which he introduced in his own department of the arts would be injustice to other distinguished characters. The encouragement to correct studies given by the Marquess Tanucci, at Naples; the protection afforded to literature and the arts at the Courts of Charles III., Leopold, Benedict XIV., Clement XIV., Pius VI. and by Cardinal Silvio Valenti, the Colbert of the Holy See; by the Albani, the Zelada and the Borgia; the studies of Mazzocchi, Bajardi, Galliani, of the two Venuti, of Maffei, Gesnero, Gori, Passeri, Paoli and Amaduzzi; the good taste diffused by Cochin, Bellicard, Burlington, Mariette and Sir William Hamilton; the Herculanæum discoveries; the travels of St. Non, Norden, Pocock, Wheeler, Spon, Revet and Stuart; the exact admeasurement of ancient architecture by Des Godetz; the masterly works of the Piranesi on the antiquities of Rome; the illustration and rendering public of galleries and museums by means of engraved copies; the opening of the baths; the study of the galleries of the Vatican; the excavation of old edifices; the collection and illustration of old inscriptions by Morcelli Marini, Zoega, Fea and Akerblad; the great works of Visconti and Winklemann; the enlightened taste of the Earl of Bristol and of the Ambassador d'Azara for these studies; the genius and profound erudition of Hancarville; the valuable collections of Hamilton, Jenkins and Agincourt; the perfection of the intaglios of Pickler; the fine and bold designs of Flaxman; the attractions given to these studies by the accomplished Algarotti; the triumph over prejudices of the formidable Milizia; the labours of Temanza and Lanzi—these are all spoken of as having supplied to Canova immenses sources of aid, and to point to the favourable moment for a different direction to sculpture from that which was then pursued by living masters.

It must, however, be admitted that the first works which Canova saw at Rome are now sunk into utter disregard, and that all trace of any inducement to excellence in them is lost. So wayward is the course of genius, and so peculiar is the road it prescribes to its progress, that the most trifling circumstances may furnish hints for improvement, but all stages of advancement are absorbed in the grand result. It is this peculiar quality of the human mind which confers the stamp of originality and leads us to attribute more to intuition than to a happy combination of circumstances united with a quick perception. It is the habit of perceiving things which are beautiful that creates a correct taste, and it is the application of knowledge under exciting influences that forms genius.

It is not a little extraordinary, and redounds in no small degree to the honour of Venice, that at the period when Canova was reviving a correct taste for sculpture in his first works in the papal city, Ottone Calderari was also successful in reforming architecture by introducing in Vicenza the Grecian taste; while Querenghi was also improving St. Petersburg by the erection of splendid edifices.

In order to afford a more powerful instance for the development of the powers of Canova, the Chevalier Zulian placed a block of marble at his command for the execution of any subject he might choose. From this block Canova executed *Theseus*, the conqueror of the Minotaur, which was so admirably performed that it was pronounced to be of Grecian workmanship on the cast of the head being produced before a party of artists and critics, assembled at the house of the Venetian ambassador. But the astonishment of these gentlemen when they were conducted before the original exceeded all bounds, and they at once acknowledged that by the work a new career had been commenced in the arts.

The three years for which the pension had been granted by the Venetian Government had now nearly expired, and the friendship of Giovanni Volpato had procured for Canova an

order to execute a monument for the celebrated Ganganelli. This order was highly flattering to Canova, yet he felt that he could not execute it until he obtained the permission of the Venetian Government as to the place of his permanent residence. In 1783, having visited Venice, he returned to Rome, where he remained during the remainder of his artistic career. The completion of his monument of Ganganelli excited the admiration even of Francesco Milizia, the most celebrated critic of the fine arts at that period.

During the progress of this great work he modelled a youthful *Psyche*, and many other beautiful works, and in 1790 his compositions in bas-relief began to appear. These performances were executed as a kind of recreation from severer studies, though no other artist had ever attempted anything in the same style.

The rapidity with which Canova worked ceases to be matter of surprise when it is known that he was not in the habit of delaying one work till he had completed another, but that while his chisel was employed on the monument of Ganganella, the clay model of that of the Pope Rezzonico, which was placed in the church of St. Peter in 1792, was in preparation.

One of the principal characteristics of Canova's works is the exquisite softness and delicacy of contour which he imparted. Unlike some other artists of the same period, he took great pains in finishing his own works. His mechanical skill was particularly useful to him in that respect, as by it he was enabled to improve the expression of his figures without incurring risk. His own hand completed what it had begun, and inferior workmen were never entrusted by him after reducing the block to the last stratum of the superficies. The lovers of art have had reason to regret the extreme anxiety of Canova in the completion of his works, as the labour and sedulous care which he used contributed to shorten his valuable existence. The use of the trapano and its constant pressure on the breast are supposed to have originated the complaint in the stomach which ultimately terminated his life. To relieve him for a time from the toils of his profession the Prince Rezzonico took Canova with him to Germany and Prussia. Canova visited Vienna and Berlin in company with this prince, and found the journey highly beneficial to his health.

The talents of this extraordinary man were not confined to sculpture, for during the interval between 1792 and 1799 he devoted his attention to painting, and executed twenty-two pictures. He then laid by this art until 1821. He does not appear, however, to have entertained a very high opinion of his own talents in this respect, but to have taken up the pencil more as a diversion from the more laborious exercise of the chisel than with any view of extending his fame. Probably devotion had some influence on his mind to induce his pictorial attempts, for he executed a large painting, of the height of twenty eight palms, for the church of Possagno, his native village, the subject being the appearance of the Eternal Father to the three Marys, and the disciples lamenting over the body of Christ.

In his personal habits Canova was regular. His declining health and his arduous pursuits alike contributed to promote abstinence rather than excess, though he was sensible of social pleasures. He was an early riser, and pursued his avocations with unabating ardour from the dawn of the morning till dusk, with the exception of the time necessary for refreshment. He usually slept a short time after meals to resuscitate nature. His evenings were spent with his friends at his own house, and he seldom went from home.

Canova disliked having pupils, not from motives of jealousy, but his avowed reason being that he did not wish to fetter rising genius with his own fame, as he was aware that any considerable proficiency in them might have been attributed to his instruction more than to their own merits. Probably, however, his own unwearied application and the vast extent of his engagements precluded him from undertaking the responsibility of instructing others in his art. He felt little annoyance from criticism, which, if just, he permitted its influence to produce amendment, but if contrary to a fair spirit of candour, he never allowed it to ruffle the serenity of his temper. He never harboured jealousy towards contemporary artists, but was the friend and patron of genius in every department of the arts. Flattery gained no ascendancy over his mind, and he possessed so excellent a knowledge of what was truly estimable in his works as to be enabled to detect their defects. In this respect he was the severest critic of his own performances, and the eulogy or censure of others were received by him without an appearance of satisfaction or disgust. A faint smile would seem to overcast his fine expressive countenance when the ignorance of some half-taught amateur occasionally exposed itself, and when any subtle connoisseur gave him credit for an excess of refinement, and in reference to some particular point in a work attributed to him credit for a minute perception or peculiarity of discrimination, Canova would coldly reply that verily he had thought of no such thing.

Canova never married, though he more than once felt the passion of love. It is probable that his devotion to the arts

supervened every other consideration, and that his mental faculties triumphed over all ideas of personal enjoyment. His whole soul was absorbed in his profession. He was also susceptible of friendship, and delighted in the contemplations of youthful days, when cares and anxieties had not embittered his life with melancholy reflections and labour and study had not exhausted his vital energies. The ardour of his nature remained unabated, and his lofty spirit soared above the sickness and infirmities of his body.

It was no less fortunate for Canova than for the arts that the political strife which agitated Europe did not affect his labours: as if by common consent all countries paid the tribute due to his genius by exempting him from the baneful influences of military despotism and warlike movements. He was required to record the actions of the great military chieftains of the day, and France and Austria vied with each other in their patronage towards him. In 1802 he was summoned to Paris to execute a monument for Napoleon, and in the interval of his journeys thither he made a second visit to Vienna to complete monuments for the imperial gardens and for the church of the Augustines. The delicacy and loveliness of Canova's female forms caused him to be called the sculptor of Venus and the Graces, and he was equally happy in his colossal groups and individual masculine characters, as is testified by his group of Theseus and the Centaur, Hector and Ajax, Hercules and Lichas, the equestrian monuments at Naples, his statues of Napoleon, Washington and of the three pontiffs.

The honours and distinctions conferred on Canova exceed any instance of the kind in the history of the arts, but it is said of him that "although decorated with the equestrian orders of many great sovereigns, decreed noble in several states, dignified by titles, enriched by pensions, honoured by important charges and functions, received with distinction at all courts, desired in all societies and associated with all the principal academies in Europe, he still preserved the simplicity and modesty of his character, and even in the usual acknowledgment of these honours which he was called on to make he avoided studiously all unnecessary pomp and ostentatious display."

The disposition of Canova was charitable, and his benevolent contributions on the foundation of the Roman Academy of Archaeology and in pensions for the support of young pupils were considerable. He also assisted in procuring books for the Academy of St. Luca and aided the funds of the Academy de Lincei. The nobleness, delicacy and secrecy with which he relieved the wants of decayed artists were distinguished equally with the munificent encouragement he afforded to youthful aspirants in their devious path of life. His active generosity in those respects frequently embarrassed his own finances. Thus were the rewards of sovereigns not confined to himself, but diffused by him as from the hands of a faithful steward to promote the happiness of his fellow-men. This characteristic of Canova was particularly manifested in 1811, when Rome, "deprived of its sovereign, deserted by foreigners, empty and impoverished, saw the votaries of Pallas and the Muses pining in their workshops without the means of support and even perishing for want." At this juncture Canova stepped forward, and with a munificent and noble spirit judiciously distributed the means of succour to the students and those who desired employment in every department of the arts.

Among the many other events of this extraordinary man, history will record with reverential gratitude his exertions on the last journey he made to Paris, when he mingled with the great personages there assembled to reclaim the spoils which the conqueror of Italy had taken from the Vatican. His re-entry into Rome was a signal triumph; "again the Transfiguration heard hymns in honour of the memory of Raphael and the Apollo and Laocoon recalled to Rome, now weak and fallen, the memory of those joyous days when, amidst the triumphal pomp of a Titus or an Emilius, the spoils of conquered nations entered her walls."

Canova always profited by his experience in the arts, and every new incident in his life seems to have afforded a hint for refining his taste as well as maturing his judgment. He was not above acknowledging the sources of his improvement even at an advanced period of life, when fame had ascribed to him established peculiarities of excellence in his art. He expressed the advantages he had derived from his voyage to England, which afforded to him the opportunity for the first time of contemplating the marbles of the Parthenon in the British Museum.

In 1821, after visiting Possagno, he returned to Rome and modelled the group of the *Piety*. In the winter of the same year he modelled a monument for the Marquis Berio, of Naples; also seven designs from the metopes of the church at Possagno. In the spring of 1822 he completed with most exquisite taste the group of *Mars and Venus* for His Britannic Majesty, and also finished for two English noblemen the recumbent statues of *The Magdalen* and *The Endymion*, in addition to which objects he continued his labours on other works previously in hand, and among various busts and other

minor works, *The Sleeping Nymph*; *Dirce, Nurse of Bacchus*; a repetition of *The Nymph Awakened at the Sound of a Lyre*, and a *Danzatrice*.

In the ensuing May, after visiting Naples to view the wax of his second colossal horse, he returned to Rome affected with a disorder in his stomach, and after a partial recovery he left the papal city for the last time for Possagno in quest of health from the air of his native hills. On the 17th of the same month he arrived at that village much exhausted by travelling, which on this, as on most other occasions with him, had been too rapid for his declining health. He remained there no longer than October 3, and on the 4th he arrived at Venice, where he intended to stay for no more than two or three days. But as soon as he had taken up his abode under the roof of the Casa Francesconi he took to his bed. His disorder continued to grow worse, and his stomach failed to perform its functions. Medical skill was useless, and could not relieve him from a distressing hiccough with which he was afflicted. He was conscious of his approaching dissolution, and received with composure the announcement to arrange his worldly concerns. He appointed his step-brother, the Abbate Giovanni Battisti Sartori, sole executor, making him more the distributor of his wealth for other beneficent purposes than the possessor of it for his personal advantage. The task was however undertaken with all the fidelity which had characterised his kind relative, who had glorified in his fame, had been the companion of his travels, and now felt more grief at his death than all his other friends.

The last days of Canova were marked with calmness and resignation. He received the offices of religion with devotional respect, and though aware that all human aid was unavailing, he took with kindness of manner the soothing remedies proffered by his friends. On these occasions he was used to say, "Yet give it me, that so I may remain a little longer with you." To those persons who moistened his dying lips he said, "Buono, buonissimo, ma è inutile,"* and his last words were "Anima bella e pura."† He spoke no more, but his countenance became radiant, and his eyes beamed with expression, indicating that his mind was engaged in some sublime conception. His death took place on the morning of October 13, having then nearly completed the sixty-fifth year of his age.

On a *post mortem* examination of his body it was discovered that his death had been caused by a paralysis of the stomach, by which the passage of the food into the intestines had been impeded.

The death of Canova created the deepest affliction throughout Venice. The patriarch himself performed the funeral ceremonies, and the members of the Academy supported his bier to the church and thence to the academic hall, the walls of which were hung with engraved copies of his works, which appeared so numerous that they seemed the labours of a whole race of artists, rather than of one man. The President of the Academy delivered the oration, which excited in the minds of the assembly the deepest emotions. The only torch which burnt beside his bier stood on that ancient bronze which had for so many centuries received the votes of the patricians in the hall of the great council, and was deemed a suitable candelabra for the last offices paid to the latter glories of the Venetian state.

At the conclusion of this ceremony the remains of Canova were removed to Possagno, and so large was the assemblage of the inhabitants of the district who attended the last ceremonies, that the prelate was necessitated to address them in the open air. All Italy mourned his death, and all Europe sympathised with her in the misfortune.

TESSERÆ.

Soil and Timber.

IT is found that the value and properties of wood vary very greatly, according to the soil and climate in which it grows; it is well known that the oak timber grown in neighbouring parishes often varies in goodness to a remarkable degree, and certain parts of England used formerly to be celebrated as yielding the most valuable ship-timber. Precisely the same holds good on a large scale, and the same tree which grown in one country affords a first-rate timber may, in another situation, yield a very inferior wood. Thus the wood of a teak-tree grown in Malabar will be decidedly superior in quality to the wood of one grown in Moulmein, and the mahogany grown in Cuba will be more valuable than the same tree grown in the swamps of Honduras. It is unnecessary to point out the important bearing of these facts on the formation and management of forests.

* Good, very good—but it is in vain.

† Pure and lovely spirit.

Vaulting in the Cloisters at Norwich.

The cloisters of Norwich Cathedral were begun in 1297, and not completed until 1430. Its four ambulatories represent four successive styles, the contrast in the details being rendered more conspicuous by the uniformity of the general design, which has been so much respected during the progress of the whole work, that even the isolated shafts, which form the proper mullions of the windows of the thirteenth century, have been continued throughout, contrary to the usual practice of the Middle Ages. The vaultings are similar in the general plan and dimensions on the four sides, but each is distinctly marked with the mode of treatment employed in the successive periods, and it is to the progressive variations in the form of the spandrels, exhibiting a gradual transition from a square section to a semicircular one, that we are now referring. In the oldest portion of the work, the eastern compartments, the horizontal section of the spandril, taken about halfway between the plane of the impost and the crown of the arch is perfectly square, and this form is more strongly developed—exaggerated, it may be said—by a slight setting back of the ribs between the cross springers and the diagonals, which gives greater prominence and a more marked expression to the angle of the spandril. In the south walk, the next in chronological order, the intermediate ribs, instead of being set back, are brought slightly in advance of the other ribs. The effect of this arrangement is to give a polygonal character to the spandril, which is, in fact, still square in its general form. In the west walk the polygonal character is fully developed and the square abandoned, but the angles of the polygon are far from being equal. In the western walk, the latest portion of the work, four centred arches are introduced, and the curves of the haunches being all alike, and the middle section of the spandril circular, the polygon formed by the front edges of the ribs is equiangular, as in fan vaulting. These effects may be confirmed by the comparison of contemporary examples, but it rarely happens that they can be found in a series and in a work of which the uniformity of design is for the most part preserved, so that changes of this kind are rather to be regarded in the light of embellishment, or as the modern improvements of the day added to the original design. Thus it is that in this respect the cloister of Norwich is so valuable by enabling us to discover many of those improvements which it is more difficult to pick out of examples complete in the character of their own age.

Early Telegraphy.

When Arthur Young was travelling in France in 1787-89, he met with a Monsieur Lomond, "a very ingenious and inventing mechanic," who had made a remarkable discovery in electricity. "You write two or three words on a paper," says Young; "he takes it with him into a room, and turns a machine enclosed in a cylindrical case, at the top of which is an electrometer, a small, fine pith-ball; a wire connects with a similar cylinder and electrometer in a distant apartment; and his wife, by remarking the corresponding motions of the ball, writes down the words they indicate, from which it appears that he has formed an alphabet of motions. As the length of the wire makes no difference in the effect, a correspondence might be carried on at any distance. Whatever the use may be, the invention is beautiful." This discovery, however, lay unnoticed for a great number of years, though the apparatus was designed to effect the same end as the electric telegraph by means very similar. The possibility of applying electricity to telegraphic communication was conceived by several other persons long before it was attempted upon a practical scale. The Rev. Mr. Gamble, in his description of his original shutter-telegraph, published towards the close of the last century, alludes to a project of electrical communication. Mr. Francis Ronalds, in a pamphlet on this subject, published in 1823, states that Cavallo proposed to convey intelligence by passing given numbers of sparks through an insulated wire; and that, in 1816, he himself made experiments upon this principle, which he deemed more promising than the application of galvanic or voltaic electricity, which had been projected by some Germans and Americans. He succeeded perfectly in transmitting signals through a length of eight miles of insulated wire; and he describes minutely the contrivances necessary for adapting the principle to telegraphic communication.

The Planning of Stonehenge.

The periphery of Stonehenge is a perfect circle: the adytum is a segment of an oval. Now the first time that a savage threw a stone into a pool of water, he would be attracted by the beauty and symmetry of those concentric outlines which would be thrown off from the point of impulse. No less would he be struck with the optical effect produced by the rotation of his sling. This would soon be followed by an operation easily effected, the tracing of a similar figure from a centre upon the sand. The process is so obvious that we have little doubt of the art of drawing circles having been attained before that of numbering to ten. No great geometrical skill, therefore, was required to draw the outline of Stonehenge. To construct an oval certainly requires some geometrical skill; more, indeed,

we fear, than the Druids possessed; but here is a considerable fallacy. For if the position of the stones in the adytum of Stonehenge be really such that Inigo Jones could mistake it for an hexagon, the result of more accurate measurements could only be that an oval might be so drawn as to come into contact with some portion or other of their vast masses. In short, it is such an oval as a gardener would tread out; a fortuitous and inartificial approach to the geometrical form.

Polychrome in Sculpture.

It is well known that the ancients occasionally added colour to their statues. The colours employed were probably never intended to increase the resemblance of the object to nature, but they served to insure distinctness or were merely for ornament. The gilding of the hair, for instance, however objectionable, would not be condemned on the ground of its being too close an imitation of real hair. So also the colour which was sometimes appropriated to the statues of *Mercury*, *Bacchus* and *Pan* would never be mistaken for flesh. Sometimes the accessories only were coloured. An epigram, ascribed by Heyne to Virgil, alludes to a statue of *Amor* with parti-coloured wings and a painted quiver. But the mixed materials of some of the statues even of Phidias, the gems inserted for eyes, and the silver nails of other figures, all indicate a practice which the taste of modern artists condemns, and which was perhaps condemned by the ancient sculptors also. In many cases religious devotion may have interfered to decorate a statue, as paintings of the *Madonna* are sometimes adorned with real necklaces and crowns. In the instance of the chryselephantine statue of *Minerva* by Phidias the Athenians insisted that the materials should be of the richest kind. Notwithstanding these facts and the difficulty of altogether exculpating the artists, it is quite certain that it was impossible to carry further than they did those judicious conventions in sculpture which supply the absence of colour. It may, therefore, be presumed that such supposed absence of colour was with the ancients an essential condition of the art, and it will appear that this condition materially affected its executive style.

Lightning Conductors.

When St. Bride's Church, Fleet Street, was struck in June 1764, the effects were described as being exactly similar to those which would have been produced if gunpowder had been pent up in the same places and exploded. A stone weighing 70 lbs. was shot out to a distance of 50 yards. Then as to the heating effects. When the New York packet was struck in the Gulf Stream in April 1827 a metal chain was knocked to pieces, some of the links were fused, and the melted iron fell in glowing drops upon the deck, which was set on fire. The metals vary considerably in conducting power. If that of lead be taken as 1, tin will be 2, iron 2.4, zinc 4, and copper 12; so that copper is the best metal for the purpose. To prevent resistance and the danger of fusion, the dimensions of the metal, whether in the form of wires or of bands, must be attended to. We have no evidence that a rod of copper three-quarters or even half an inch in diameter, or an equal quantity under any other form, has ever been fused by a stroke of lightning. But when the lightning seizes on smaller portions of metal, such as the bell-wires of a house, the conducting power not being sufficient, they often become heated to such an extent as to be dissipated in oxidised vapour. Guided by what we know respecting the laws of conduction, but chiefly by the examination of a large number of reported cases, the dimensions of conductors have been determined. Copper tubing from 1 to 2 inches in diameter, made of metal of about one-fifth of an inch in thickness, may be used. The tubes may be made in lengths of 10 or 12 feet, so as to be screwed end to end, and they may be attached to the masonry or brickwork by means of rings or flanges fastened with copper nails. But as copper is a costly metal, and as such liable to be stolen, iron, although a five-times worse conductor, may be used. If galvanised it will resist the weather. Wrought-iron tubing 2 inches in diameter, made of metal three-quarters of an inch thick, and arranged to screw together in lengths, would answer the purpose. It may be fixed by couplings of cast-iron. If a solid rod be used it should not be less than three-quarters of an inch in diameter. In many cases the conductor may be in a straight, continuous line, projecting in a point like that of a bayonet a few feet above the kitchen chimney, and terminating in a forked metal branch in the earth to the depth of a few feet, or if practicable in a well or a wet drain. If there be any metal water-pipes or other masses of metal about the building it would be desirable to unite these with the conductor by means of metal ties. The conductor should be fixed to the building, not detached from it, and on no account be insulated by glass rings or pitch, as is sometimes done. If the building be of considerable extent a conductor should rise from each prominent point, and all the conductors be connected by means of metal ties with each other, and with the lead or zinc roofs, vane spindles and water-pipes, the main point being to secure capacious and good metallic conduction from projecting points of the building to the earth.

MR. W. G. ROWAN, ARCHITECT.

NEW BUSINESS PREMISES, WATERLOO STREET, WESTON-SUPER-MARE.

THESE business premises have recently been erected in Waterloo Street. The facework of building is executed in Corsham Down freestone, the pilasters being of red Mansfield. The brickwork in gables is executed in bricks supplied by Messrs. POULTON & SON, of Reading. The work was executed by Mr. J. WILCOX, local builder, from the designs of Mr. SYDNEY J. WILDE, architect, of Weston-super-Mare.

DESIGN FOR CLOCK TOWER, CITY OF NEW SARUM.

THIS design was submitted in the competition for the new clock tower to be erected partially upon the old town wall, shown in light tint at plan level A. No bell was permitted, and height of illuminated dial restricted. The elevations were to have been in Chilmark stone, coverings in red flat tiles, and aprons, flashings, drips, weathercock, &c., in copper. The design is, by Mr. JOHN W. RHODES, architect, Mitre Court Chambers, E.C.

CATHEDRAL, RATISBON.

PLUMBING.*

By JOHN HONEYMAN, A.R.S.A.

IT is generally interesting, and often instructive, to look back on the course of events which have led up to the existing development of any movement, institution or occupation. The saying is old and trite that "experience teaches fools," and he must be a fool indeed who despises the instruction of such a monitor. Indeed, in this connection—our relation to experience—and in the sense of the word "fool" here intended, which is rather "novice" than "stupid idiot," we may readily admit the truth of Carlyle's doctrine that people are "mostly fools," and even venture to assert that there are no exceptions, for if we sit at the feet of experience till our last hour we shall still find our lesson incomplete. I am in hopes then, gentlemen, that although I may not say much that is new to you to-night, my reference to things of the past may not be unsuggestive, for wisdom is to be drawn from conspicuous failures as well as from conspicuous successes. I think a brief reference to the vicissitudes of sanitary science during the last forty years, and the many changes which have been introduced into plumber-work, can hardly fail to be interesting to such an audience as I have now the honour to address, and I trust it may, in some measure, be useful. I propose to limit my retrospect to a period of about forty years, beginning with the time when, as an embryo architect, I wielded the T square in the office of a gentleman who has long since left us, but who will be remembered by some of you—the late Alexander Munro. Since that period enormous progress has been made in every department of mental and manual activity; but the progress observable in plumber-work during the last half century is not so much in the direction of superior workmanship as in the adaptation of apparatus to new requirements. Sanitary science has dictated many changes in ordinary domestic appliances, which plumbers have—rather tardily, if the truth must be told—recognised to be advantageous, and modified their practice accordingly. The new requirements naturally led to the introduction of new apparatus and to the production of many things by machinery formerly made by hand, and the manufacture of fittings for the use of plumbers has in this way been carried to great perfection, but the plumber trade can hardly claim much credit for progress in this direction. Plumbers, with a few conspicuous exceptions, have not been great inventors. I think I may very safely say that, even in recent times, the most perfect appliances have been known to be associated with very bad plumber-work, while the converse is also true. In the building trades generally there is little room for progress such as we find in other departments of skilled labour. We find as good masonry in our cathedral as we are able to produce now, and I have no doubt the man who "rolled" together the cast sheets of lead on its roof would handle in a tradesmanlike way the soft-milled sheets on a modern platform. But one reason why improvement in plumber-work is not so marked as might be expected is that forty years ago we had remarkably good plumbers here. There has been greater improvement in England than here, but the reason of that is that there was much more room for it. Scottish plumber-work was of a distinctly superior

character, both in design and execution, and the most probable explanation of this, I think, is that the trade here was, as a whole, better educated. It very rarely happened that any lad apprenticed to a skilled trade was illiterate, and both journeymen and masters were well educated. But while forty years have made little change in the character of the plumber's work in Glasgow, they have made a vast change in two respects—(1) the development of the trade; and (2) the diffusion of correct views regarding the methods of securing the best sanitary results, and the responsibility of the plumber in connection with the health of the community.

I think the development of the building trade has more than kept pace with the growth of the city, and there is a keener competition for work now than there used to be. That is certainly the case in my own profession. Some of you will remember all the architects of any standing in the early fifties—there were about 16 altogether, and in the last "Directory" we find no fewer than 138 names. Then in the "Directory" of 1854, one of the first I purchased for my own use, I find that the list of plumbers occupies half a page, 51 names in all, whereas in last year's "Directory" the list occupies eight pages—comprises 378 names—an extraordinary change to occur within the recollection of many who are here present. I am aware that some of these are rather bellhangers and gasfitters than plumbers, but we may safely take the number as over 300. And here I may remark that I have a considerable respect for the old adage, "Let the shoemaker stick to his last." The plumber, strictly speaking, has to do with water only. He has to protect us from the water which comes down from above; he has to supply us conveniently with the waters we daily use, and he has to remove these waters, when used and laden with impurities, as quickly as possible from our dwellings—a large and important function. But to return, when one looks at a list such as this (in the "Directory") he cannot fail to be deeply impressed with the vast importance of the problem, How shall the energies of this great multitude of plumbers be so directed and governed as to insure that they do not work mischief to the public health? For we must remember that it is not merely the masters (whose names appear on these pages) with whom we have to deal, but the greater army of journeymen and apprentices in every shop, who are from day to day in every quarter of the city—in costliest mansions and humblest tenements—doing, according to their lights, either good or evil. Is it not true that many of these, indifferent to the result, are quite content even now to go on doing things by what we call "the rule of thumb?" But there are undoubtedly symptoms that "the rule of thumb" is becoming gradually discredited. This is one of the most encouraging facts connected with the present. The operative plumber has been roused to a sense of the growing comprehensiveness and complexity of his craft, and of the advantage, if not the necessity, of technical education of a wider and, at the same time, a more exact character than sufficed in former years, and it is a most fortunate circumstance that, just as this need becomes felt and pressing, facilities for supplying it increase and encouragements are multiplied. It cannot be questioned, I think, that in this connection the movement set on foot by the Worshipful Company of Plumbers has done notable service, and I trust the day may not be far distant when no respectable plumber will be contented unless his name appears on the official register.

The three things which during the last forty years have done most to stimulate the plumber trade in this district were—the introduction of the Gorbals gravitation water, the introduction of the Loch Katrine water, and the growth of the shipbuilding trade, especially the construction of so many magnificent passenger steamers here, with their luxurious fittings.

Let me refer very briefly to our water-supply. When the Gorbals works were completed nearly fifty years ago, it was becoming evident that it would very soon be necessary to give up the river as a source of supply, and these works conferred a great boon on the inhabitants of the south side, who were so well pleased with their supply that when the Loch Katrine scheme was proposed they resolved to oppose it. The true reason of their opposition, I have no doubt, was that they were afraid of additional water rates, and they thought it unfair that they should be charged for what they did not want. Ultimately things were satisfactorily arranged, and for some years after the introduction of the Loch Katrine water the people on the south side continued to pay a rate of one shilling in the pound, while those on the north side paid from 1s. 2d. to 1s. 4d. In 1865 the rate was equalised at 1s. over all, and in 1871 it was reduced to 8d.

It is a curious fact that the opponents of the Loch Katrine scheme relied chiefly on the contention that the water of the loch was too pure, and that by contact with lead it would become highly poisonous. The late Dr. Penny, of Anderson's College, a well-known analytical chemist, gave evidence to this effect before a parliamentary committee. And I remember seeing some of his specimens, which were certainly well fitted to create alarm—the lead suspended in the Loch Katrine water being greatly oxidised. I don't know exactly how this was got

* A paper on "The Plumber Trade: a Retrospect and a Forecast," read at Glasgow, and reprinted by permission of the Worshipful Company of Plumbers and the West of Scotland District Council.

over, but I suppose some other chemist must have proved that it was of no consequence, and I am not aware that we have any large mortality from lead-poisoning. One thing is certain, that the water was very soon brought into contact with a large quantity of new lead, for not only was it found that the old pipes were unable to stand the new pressure, but the demand for new supplies rapidly increased. Some idea of this may be gathered from the fact that in 1856 the total revenue, with a rate of 1s. 2d., was 62,335*l.*; whereas thirty years afterwards, with a rate of only 8d., the revenue was 162,572*l.*, and a sinking fund of 141,931*l.* had been accumulated.

With reference to the growth of sanitary knowledge, that has been a very slow process. For many years after the introduction of the system of water carriage we were simply groping in the dark. Microbes and bacilli were fortunately unknown in those days, so the bad sanitary arrangements did very little harm. While waterclosets were still comparatively rare, the prevailing idea seems to have been that all the water had to do was to take the soil out of sight; and, in point of fact, much of it never got beyond the built drains and the invariable cesspool, and the river remained uncontaminated. The regular fishing of salmon on the Clyde, just as on the Tay at the present day, is a thing quite within my recollection; often have I watched the whole process at "The fishers' hut," within a mile of Glasgow Bridge. I remember very well when, as a boy, passing up or down in the "steamboat," it was quite a common thing for her to slow or stop altogether several times between Dumbarton and Glasgow while the nets were drawn clear of her course. In those days our supply of water in Glasgow was drawn partly from pump wells, but chiefly from the Clyde, and there was very little plumber-work in our houses. In the country generally there was practically none, and I may almost say that the plumbers, by their improved methods, are responsible for the filthy state of our river now. I used sometimes to live in a nice little cottage at Govan, which stood where the new graving-dock now is. It had a small flower-garden in front and a large garden behind, the gooseberries and pears of which I remember to this day. A narrow road passed in front, and then a beautiful green common sloped down to the towpath along the river, which here took a sharp turn to the north. On this common stood a pump-well, to which the maids and matrons of the village resorted with their "stoups" for their daily supply of water. I need hardly say that in that happy village, where almost every cottage was thatched, there was no need of plumbers, and there was no river-pollution by Govan at least. The cottage I have described being of rather a superior class had a pump-well of its own. This stood close to the back door, with a large semicircular trough in front of it, cut out of freestone, having a grating in the bottom. There was absolutely no other plumber-work about the place, and the same might be said of almost every other house of the class throughout the country at that time. The trough in front of the well was the sink of the establishment, and where the waste water went or how much of it got into the well again I have not the least idea. The water was beautiful to look at, clear and cold, and this much must be said for this old style of thing, that I never heard of a case of zymotic disease being in that house, and the old lady who was there in my boyhood lived there to be over eighty years of age, and her large family grew up to be the fathers and mothers of a generation which has been delivered over to the tender mercies of plumbers. The transition from such a primitive state of matters as I have depicted to the present complex development of domestic plumbing was a very gradual process. The difficulties and dangers involved in the change were not at first understood, although they very soon became apparent. The first difficulty which met the sanitary innovator of the day was the inefficiency of the drains formerly in use for the conveyance of sewage. It was soon discovered that ordinary built drains of brick or rubble were not suitable, although they continued to be used for many years and, I have no doubt, some are in use in Glasgow to the present day. I have seen a built drain which did answer the purpose very well. It was made entirely of hewn stone, with a channelled sole on which the sewage flowed, but such a drain was very costly and beyond the means of most people. The defect of the rough built drains, of course, was that they leaked. The liquid sewage escaped and very often found its way into the wells, which continued to be used, and sometimes were the only source of water-supply long after the introduction of waterclosets; but, notwithstanding this serious defect and the inconvenience it caused—for danger was apparently not taken into account at all—so late as 1860 I saw the drains in the streets of a town not fifty miles from this constructed thus. Rough slabs of the native slaty rock were laid together at the bottom of the trench to form the sole of the drain; along the ends of these were built the rubble sides, and similar rough slabs laid on the top formed the cover. The streets were long and the gradients very slight, and I need hardly say that, in process of time, it was found that these remarkable common sewers had never acted as drains at all, but merely as elongated filtering tanks, in which all solid matter was retained. When

this discovery was made, they were replaced by drains of a different type; but that a body of intelligent men should have done anything so foolish only about thirty years ago is a curious illustration of the slowness with which correct ideas on the subject of drains grew. The invention of glazed fireclay pipes greatly facilitated the construction of good soil-drains at a moderate cost; and although till quite recently far too little attention was paid to the proper pointing of these, it may be fairly said that these fireclay pipes solved the difficulty of the water-carriage of sewage.

The next stage in the progress of domestic sanitation was the growth of the idea that defective drains, and, ultimately, that all drains, were a source of danger to the dwellings to which they were connected. This led to the invention of traps and the abolition of the old built cesspool. The form of trap used for many years (and still manufactured) was the familiar syphon trap with the cleansing eye in the centre. When properly made, it served to cut off the connection between the house and the common sewer—a very important service, and all that was required of it, for the idea of ventilating the drains and sewers had not yet dawned on the sanitary engineer. I was not by any means the first to direct public attention to this subject, but in 1858 I invented and publicly exhibited a trap which greatly facilitated the ventilation both of drain pipes and sewers. Instead of the eye in the centre, it had an eye on each side of the water seal, either of which, or both, might be used for ventilation as might be required. The cleansing eye was on the side next the house, and the surface of water exposed on that side was considerably less than on the other, the run-out of the trap being different from the drop into it. Indeed the various traps now in common use having the eye on the house side of the seal are but very slight modifications of my design, which was probably the first of the kind applicable to drains. It is figured in the first edition of Dr. Parke's well-known work. But here again I must remark that progress in the direction of ventilation was exceedingly slow. For ten years after my lecture and the exhibition of the new trap before the late Mr. Carrick and the principal Glasgow architects and builders of the day, I do not believe a single two-eyed trap was used except by myself. The man who did most to demonstrate the utility and practicability of drain ventilation here was undoubtedly our friend Mr. W. P. Buchan, and that, I may say, brings us down to the present day, when the proper ventilation of all sewage drains and soil pipes is regarded as a *sine qua non*. One of the most important changes made to facilitate ventilation was the carrying up of the soil pipe through the roof and leaving it open. In days of old it ended at the trap of the closet, with the result that the confined gases ate a way through the lead bend and so had free access to the house. The late Dr. Fergus used to have quite a collection of these honeycombed traps, and I have no doubt that many hundreds remain in use now.

I may here say that I think a good deal of the recent progress of plumber-work is due to the existence of our sanitary protection associations. These have been a great means of bringing home to the public the fact that drains may be in a very bad state, although there is no perceptible smell and although landlords and especially landladies protest, as they always do, that the drains are in perfect order. One result of this is that it is becoming customary for tenants to insist upon seeing a certificate from the sanitary engineer before taking a house or even furnished apartments. If this custom became universal it would have a most salutary effect, and make things very lively in the plumbing trade for some time to come.

The admission of air to a house through the drains is on many grounds exceedingly objectionable, but it is undoubtedly of more importance to make the drains and plumber-work water-tight than air-tight. Organic matter must be removed quickly and perfectly without one atom being left behind to ferment or evaporate within the walls. If this is effected and the drain disconnected from the common sewer, the drains are practically innocuous. The relative importance of the two things has been rather lost sight of. The air from drains is a very bad thing, if the drains it comes from are badly ventilated and full of putrefying matter, but in that case it would be a very stupid course to attempt mere palliatives; the right thing to do is to make the drains clean and wholesome. If the sewage of a house were taken across the basement in an open channel it would do no harm to the inmates provided the channel was smooth and impervious and had a good fall. The covering of such a channel is a matter of convenience, not of sanitary necessity. But while air may, in certain circumstances, enter a house from its drains without serious consequences, the other contents of soil drains cannot do so without serious risk. That is the point I wish at present to impress upon you.

You will not understand me to imply that it is of no consequence whether drains are ventilated or not; for even if there be in them no micro-organisms worth speaking about and no germs of specific disease, there are other things which, by universal consent, are held to be deleterious, having an

atonic influence predisposing to certain forms of disease. There is, therefore, no question about the expediency of ventilating drains and sewers; but it will serve no good purpose to exaggerate its importance, for exaggeration is a species of falsehood and is apt to distort our mental vision, causing us to form false estimates of the relative importance of things, and, in point of fact, I have seen cases where the means taken to effect disconnection and ventilation—the multiplicity of Buchan traps and Hart traps and grease traps of one kind and another—seriously interfered with the primary object of all domestic drainage; the immediate washing away of all the organic matter and waste water we commit to the drains. You will, therefore, I dare say, agree with me that on this point a word of warning is not uncalled for. Regarding the matter from the practical point of view, my experience has long since led me to the same opinion which Dr. Carmichael has reached by more scientific methods, namely, that sewer-gases, as they are called, do not, and indeed cannot, originate specific disease. It is true that when typhoid fever or diphtheria has occurred in a house and the drains are tested, they are very often found defective, but they are also sometimes found to be in perfect order; and among the healthy houses you will not find a larger proportion with perfect drains than among the unhealthy houses. In both cases the percentage of defective drainage is exceedingly high even now, and what must it have been thirty years ago? If the air of the drains were laden with pathological germs, none of the last generation could have survived. I have lost faith in the virulence of the healthy bacillus; but, at any rate, it is an ascertained fact (*vide* Dr. Angus Smith at Glasgow Congress of Sanitary Institute of Great Britain; Report of Dr. Dixon's Committee on Air of Glasgow to Philosophical Society; paper by Dr. J. S. Haldane, Transactions of Sanitary Institute, vol. ix. p. 407, &c.) that there are not nearly so many micro-organisms in the air of sewers as in the air of ordinary apartments, or even in the external atmosphere. It would almost seem that the existence of micro-organisms in the sewers is due to the ingress of fresh air, not to the existence of sewage. Upon the whole I am inclined to think that the bacillus is very much maligned. It is in itself a very harmless creature, but "evil communications corrupt good manners." You have often heard of people being killed by the bite of a fly. Well, in cases of that kind the flies may be caught, and they may be identified as belonging to the same species, and if people did not know better, they might conclude that this species of fly possessed the specific virus of anthrax. In the same way you know that a scratch from a sharp steel knife causes little inconvenience; but if the scratch is made by the knife you are using in the dissecting-room the effect is very different. The steel is harmless, yet deadly when in contact with certain poisons. So is it, I venture to think, with the bacillus—at least, this theory seems not to be inconsistent with the results of experience and recent investigation. We may thus charitably believe that if the bacillus, which belongs to that most beneficent order of beings, the scavengers, is sometimes the vehicle of disease, it is only accidentally so. But I must not pursue this subject further here; it is a digression rather beyond the plumber of the past perhaps, but quite within the range of the scientific plumber of the future.

Before concluding this brief reference to present practice I would like to say that I notice one or two things which are still done by plumbers, if left to their own devices, in a way which can hardly be commended. I shall not particularise, as I am not to lecture you in the sense of "blowing you up" to-night, but I may remark that the shortcomings I refer to point to the desirability of the plumber of the future attending some of our classes of building construction, a science for which plumbers often show supreme contempt.

There is another thing which the plumber of the future must know a great deal more about than the plumber of the past, and that is the nature and use of different metals. You have now to use many metals for a variety of purposes, in various combinations and subject to both chemical, mechanical and electrical action, and you must understand these things if you are to do good work intelligently; and allow me to say you will never do work which will yield you any delight in the doing of it if you cannot do it intelligently. I would therefore strongly urge any young men whom I now address to avail themselves of the many facilities which are now within their reach for obtaining this technical knowledge, so that they may rise to the proper level of the modern skilled mechanic. We know not what possibilities connected with the plumber trade lie before you, but this we know, that between the man who blindly labours at his daily task without one thought beyond his daily wage and he who understands his work and delights in it, there is all the difference between a galley-slave and the stroke of an Oxford eight. You may depend upon it, gentlemen, that it is knowledge which truly emancipates, and which alone can lead us to make any sense out of the phrase, or to bring the truth of it home to our individual experience, *Labor ipse volupias*.

I regret that so little time remains for reference to one

important part of my subject—which, however, I must not entirely pass over—namely, the change which has occurred within the period under review in wages and the hours of labour. When I commenced business, the standard wage of a plumber was 23s. 9d. per week, and the hours of labour were 60 per week. In winter the hours were the same on Saturdays as on other days, but in summer the plumber, by working 10½ hours on other days, managed to get away at 2.30 on Saturdays. Now, at the present time, the number of hours of labour per week is only 51, and the week's work ends at one o'clock on Saturdays, and the wages, instead of being (as they would be at the old rate) only 20s., are 34s. There is evidently remarkable progress here; but is it in the right direction? Yes, I think there can be no question about that, and I am sure all here are unanimously of that opinion. Fifty-one hours per week is a very near approach to the ideal eight hours per day. It is a fair amount of work if that work is honestly performed, and yet it leaves a fair margin of leisure. I often wish I had as much myself, especially when sometimes hurrying along just in time to catch a five o'clock train on a Saturday afternoon, I find my way blocked by groups of workmen sauntering along in a very leisurely manner, with the air of men in easy circumstances. And no doubt, as compared with their predecessors, they are in easy circumstances, both in respect of toil and wages, for almost every necessary of life is a great deal cheaper than it was forty years ago. There was no 4 lb. loaf at 5d. in those days, nor sugar at 2d., nor tea at 1s. 9d., nor—may I mention it—any "butterine."

But, gentlemen, I fear we cannot say that the progress of the master plumbers has been quite as satisfactory. There were really wealthy plumbers in the old days, and it was quite possible to make a fortune at the trade; but now profits have greatly diminished, and it is a laborious job to get through enough of work to make a decent living. Now, is this an entirely satisfactory state of matters? That is an extremely interesting question for those interested in the plumber trade. We are not likely to be unanimous here, for the answer must depend on our particular point of view. Some there are who hold that masters as a class should be abolished; others apparently think that they should not be abolished, but only persecuted; while others cling to the old-fashioned idea that, upon the whole, they are still indispensable, and that they ought therefore to be supported and encouraged. To this latter class it must be discouraging to know that the inducements to assume the position of master are becoming year by year less and the deterrents greater, while to the others these facts must be regarded with satisfaction, as among other things indicating the approach of a new era in which the workman shall be master of the situation. It must be admitted that during the last thirty years events have distinctly tended in this direction, and I confess that for myself my sympathies are with those who desire to see the wealth-producer reaping the full reward of his toil, but I have no sympathy whatever with the methods hitherto pursued in furtherance of this object. What I would say to plumbers and to skilled workmen of every kind is this:—While you have masters treat them well, your interests are indissolubly bound up with theirs; but when you see your way to do without them, to manage your own affairs—converting, it may be, quondam employers into employés—then, I say, go forward in a self-reliant, straightforward, manly fashion, scorning to claim privileges while you refuse to accept relative responsibilities.

I cannot help thinking that the bill at present before Parliament for the Registration of Plumbers may facilitate such a revolutionary movement as I have just indicated, giving, as it does, legislative recognition to a great union of men all possessing a certain standard of skill in their trade. Who knows what the functions of District Councils may be thirty years hence? But whatever changes are before us, of this I feel assured, that the great labour problem, which is at present engaging the attention of so many minds, shall never be solved till the working classes recognise the fact that their destinies are in their own hands, if only they have the capacity to shape them by efficient co-operation. There is no other practicable solution of the problem. Be assured that the great socialistic fabric of the future—which so many desire—if it is ever to overshadow our land, must rest on some better foundation than the treacherous quicksand of coercion; it must be the work of free men who can trust each other, and must rest on the solid basis of the immutable precept—"Whatsoever ye would that men should do to you, do ye even so to them."

A Pulpit has just been completed in St. Peter's Church, Peel Causeway. It is octagonal in form, and has been designed to correspond in style with the reredos which was erected last year. It is ascended from the chancel level by three steps, which are protected by a light pierced balustrade. The whole is executed in rich variegated alabaster, and has been made from the designs of Messrs. Tate & Popplewell by Messrs. J. & H. Patteson, Oxford Street, Manchester.

QUEEN ELIZABETH'S BATH.

AN interesting subject for an architectural paper could be found in the history of the transformation by which an odd assemblage of buildings became Trafalgar Square, which so many are pleased to accept as the finest site in Europe. The sketch below represents the interior of one of the buildings which was comprised as part of the King's Mews. It was nearly square in plan, the interior being 13 feet by 12 feet 6 inches, and was constructed of fine red brick. The most interesting part was the massive groining of the roof. The building was commonly known as Queen Elizabeth's Bath.

Scottish Academy, where he had four water-colour drawings hung. One of these was a drawing of the Crown Tower of King's College, Aberdeen. In 1870 he began practice in Elgin, and during the first seven years of his professional career he was the designer of many public buildings, including the City of Glasgow Bank, the restored picturesque old Scottish Town House, and several churches, schools and private residences. In 1877 he became partner with Mr. Matthews, Aberdeen, and took up his residence in the city. He has expressed himself most freely in a robust version of the Renaissance style, broadened a good deal by the almost invariable use in Aberdeen buildings of granite. His designs in the city include those of the Northern Assurance Office, the ornate

QUEEN ELIZABETH'S BATH.

THE NEW ASSOCIATES OF THE SCOTTISH ACADEMY.

AT the special assembly of the Royal Scottish Academy, which was held last week, the following gentlemen were elected Associates:—Messrs. Alex. Marshall Mackenzie, architect, Aberdeen; R. B. Nisbet, painter, Edinburgh; W. Birnie Rhind, sculptor, Edinburgh; John James Burnet, architect, Glasgow; C. G. H. Kinnear, architect, Edinburgh; Alexander Roche, painter, Glasgow; Henry W. Kerr, painter, Edinburgh; John Kinross, architect, Edinburgh; David Robertson, architect, Edinburgh; and J. Coutts Michie, painter, Aberdeen.

The *Scotsman* gives the following biographies of the new Associates:—

Mr. Alexander Marshall Mackenzie is a Morayshire man. He was born in Elgin forty-five years ago, and is the son of the late Mr. Thomas Mackenzie, an architect of recognised talent, whose reputation still lives in the North. Mr. Mackenzie, who is a brother of Sheriff Mackenzie, of Caithness-shire, received his education at Elgin Academy, and afterwards at private classes in Aberdeen. His architectural training was acquired in the office of Mr. James Matthews, who had previously been in partnership with his father, and afterwards with Mr. David Bryce, R.S.A., Edinburgh. While studying in Edinburgh Mr. Mackenzie was an exhibitor in the Royal

Art Gallery Buildings in Schoolhill, the Harbour Offices, the Grand Hotel, additions and alterations to the Palace Hotel, and massive blocks in Union Street and Bridge Street. One of his works outside the county is that of the fine new Elgin Town Hall. Quite recently he prepared designs for the new church at Crathie, and these Mr. Mackenzie had the honour of submitting to the Queen at Balmoral for her Majesty's approval. Among the more recent churches he has designed in or near Aberdeen are those of Craigiebuckler, the Free South, Free Trinity, Free St. Clement's and Ruthrieston Parish. But Mr. Mackenzie's greatest work in Aberdeen is undoubtedly the reconstruction and extension of Marischal College buildings, the scheme for which involves the expenditure of 80,000*l.*

Mr. R. B. Nisbet, who is a native of Edinburgh, commenced life as an apprentice in a Leith shipping office. He took to art in 1879, and went with his brother Pollok to study at Venice. Returning, he joined the Board of Manufactures School, where he studied from the antique and the life. His first exhibits at the Royal Scottish Academy were in oil, but soon he took entirely to water-colour, and now he has altogether relinquished the former medium. In 1885 he went with Mr. P. W. Nicolson to Cromarty, where he first fell in love with bents and sandy dunes. Since then he has sketched mostly at Gullane, St. Andrews, North Berwick, the Fifeshire coast, at Selkirk,

Surrey, and Yorkshire. At Surrey he got his idea for the picture the Chantry Fund purchased in 1890. He first exhibited in the Royal Academy in 1888, in which year he was elected to the Royal Society of British Artists. Last year he was elected to the Royal Institute of Painters in Water-Colours, and he is also a member of the R.S.W. He exhibited at Dresden and Berlin last year, where he gained a diploma, and he has been specially invited to send work to Vienna and Chicago. He leans to the romantic side in his art, but is catholic enough in taste to admire all sides. He owes his style chiefly to strong admiration for the works of De Wint, Cox and Cotman, in water-colour; and Chrome and Constable, along with the Barbizon school, in oil. Some of his principal works are:—*Evening Stillness, Solitude, Harrowing, Forenoon* (purchased, along with many others, by the Royal Association for the Promotion of the Fine Arts in Scotland), and *Sunset on a Border Moor*. Along with Mr. Robert Noble and other members of the committee, he has taken an active part in the formation of the new Society of Scottish Artists.

Mr. Birnie Rhind comes of an artistic family, being the son of the late Mr. John Rhind, A.R.S.A. From his childhood, being constantly amongst his father's work, to follow his parent's footsteps became the natural bent of his early years, and to his father he is indebted for a thorough and comprehensive training as a sculptor. He entered when quite a lad the School of Design, where he studied for several years, afterwards passing four or five years in the R.S.A. Life School. He exhibited first in the annual exhibition of that body in 1877, though it was as a painter for the first two or three years. Since then he has been a regular exhibitor in the sculpture-room. In 1881 he competed with other Scottish sculptors for the statues of the Scott Monument, and was successful in obtaining commissions for four of the leading figures. Later he gained the competitions for the public memorial to the St. Anne's lifeboat disaster, and for the monument to commemorate the raising of the 42nd Regiment at Aberfeldy, and also the first premium in the Chambers statue competition. Like his father, he has made decorative figure sculpture a special study, with the result that, in addition to being associated with the late Mr. Rhind in many of his leading commissions, he executed himself many public works, among them being a large pediment, with Scriptural subject, for the church of St. George's-in-the-Fields, Glasgow; all the figure sculpture on the Charing Cross Buildings in the same city; the colossal group of Britannia over the Academy, Perth; the figure pediment of the Leith Dock Commission offices; the statue of Queen Margaret in the Portrait Gallery; and the pulpit just recently erected in the Episcopal Church, Haddington. Ideal sculpture has also had his attention, as witness his spirited military group, "Tel-el-Kebir," exhibited some years ago, and, in last year's show of the S.S.A., a statue of Burns in marble. In portraiture he has for many years shown good examples, prominent among them being the late Mr. Gibson Thomson. Latterly several of his fellow-artists have been among his sitters. At present he is engaged upon the sculpture for the doorway of the Scottish National Portrait Gallery, which when finished will be a very elaborate piece of work. Several of the models are in the Royal Scottish Academy's Exhibition. The ladies of Edinburgh have entrusted him with the Queen Mary group for the large niche in the east gable of the same building, which they are presenting. He is also engaged on a colossal statue of the Thakore of Gondal, to be erected in the capital of that prince's dominions. Of monumental art he has just completed a mural tablet, with bronze portrait medallion, to mark the burial place of William Drummond, of Hawthornden. The beautiful memorial to the late Lord President Inglis, for St. Giles, designed by Dr. Rowand Anderson, is being executed by him, and for the same architect he is engaged on some sculpture for an important reredos in the west country. In Glasgow, Mr. Rhind is just completing a series of allegorical bas-relief figures in Sauchiehall Street, and the Sun Fire Insurance new offices in Renfield Street are to be decorated with important figure sculptures from his chisel.

Mr. John James Burnet, architect, was born in Glasgow thirty-five years ago, and is a son of the late Mr. John Burnet, a very widely-known architect. The new A.R.S.A. was trained in his father's office in Glasgow, subsequently going to Paris, where he entered the studio of Mr. Pascal. After examination he was admitted to the Ecole des Beaux-Arts, where he gained two medals—one for mathematics, and the other for construction. Returning to Glasgow, he resumed work with his father, and won the competition for the Art Galleries now in Sauchiehall Street. In Glasgow the other public buildings of importance which he has designed are the Clydesdale Bank, the Union Bank, the Clyde Trust Buildings and the Athenæum. In Edinburgh his work may also be seen in the Drumsheugh Baths and the internal reconstruction of the United Presbyterian College, while he also was the author of the design from which the Edinburgh Exhibition of 1886 was erected. In that year Mr. Burnet was elected a member of the Edinburgh

Royal Society. In Gothic work Mr. Burnet was the architect for the Glasgow Barony Church, one of the finest ecclesiastical structures in Scotland, and also two beautiful little churches in Arran. He has taken a great interest in the designing of plans for working-men's dwellings, and his work in this direction may be seen in Rottenrow, Glasgow. His firm at present are also engaged on a Pathological and Bacteriological Institute for the Western Infirmary, Glasgow, and the extension of the Students' Union at Gilmore Hill. Mr. Burnet's firm is known as John Burnet, Son & Campbell.

Mr. C. G. H. Kinnear, 12 Grosvenor Crescent, Edinburgh, partner of the well-known firm of Messrs. Kinnear & Peddie, is one of the leading architects in Scotland. He was a pupil of the late Mr. Bryce, has been in business since the end of 1855, and is the designer of many of our finest mansion-houses, churches and public buildings. For many years Mr. Kinnear has been a most active volunteer, and as colonel of the M.C.A. was on Saturday last the recipient of the volunteer officers' decoration.

Mr. Alexander Roche is an artist who has helped largely in exalting the name of Glasgow in the art world. His paintings are full of the breath of impressionism without the eccentricity which characterises the more advanced apostles of that school of art. He was born in Glasgow, and received his art education principally in Paris under Boulanger, Lefebvre and Gerome. For many years he has exhibited at the Glasgow Institute, the Royal Scottish Academy, the Royal Academy, the English Art Club, the Paris Salon and Munich Exposition. His best works are *The Good King Wenceslaus, Shepherdess, The Hill-top, Miss Loo, Scottish Town, The Clyde, A Pastoral and Off to the North (St. Monans)*. His decorations include a second-class gold medal at Munich in 1891 and honourable mention at the Salon in 1892 for *The Clyde* mentioned above.

Mr. Henry W. Kerr, though a native of Edinburgh, received his early education in Dundee, where also he was apprenticed to a manufacturer on leaving school. Subsequently he entered an office in Leith in order that he might have a better opportunity of attending the arts classes of the Board of Manufactures and the Life School of the Royal Scottish Academy. Water-colour is the medium in which he has always worked, and throughout his career he has exhibited publicly only one oil-painting. He made his first appearance in the annual exhibition of the Academy in 1883, his contribution on that occasion being a small water-colour drawing. It was not, however, till two or three years later that he came prominently into notice with a drawing entitled *A Morning Salutation*, which, after being shown in the Academy galleries, was purchased by Mr. J. L. Toole at the Glasgow International Exhibition. Since then the most important pictures he has painted have been *The Kirk Collection* and *The Loupin-on Stane*, and this year he is represented in the Academy's exhibition by a work of much merit, entitled *St. Patrick's Day in the Morning*. He is specially successful in representing scenes of Irish peasant life, and in rendering in a sympathetic and appreciative spirit the best aspects of the Hibernian character.

Mr. Kinross, though a native of Stirling, has been engaged in architectural work in Edinburgh since the year 1874. For six years after coming to the city he was engaged in the office of the then firm of Messrs. Wardrop & Reid. Subsequently he studied in Italy for some time, and on his return he published a work, "Details from Italian Buildings, chiefly Renaissance." Among the principal buildings which Mr. Kinross has designed are the mansion-house of Thurston, near Dunbar, the property of Mr. Richard Hunter, and St. Peter's Church, Fraserburgh. He has also been engaged in work at Manderston for Sir James Miller, Bart., and at present he has charge of the restoration of Falkland Palace for the Marquis of Bute. Mr. Kinross is in his thirty-seventh year.

Mr. Robertson is a son of a former City Chamberlain of Edinburgh. Among the buildings in the city which he has designed is Morningside United Presbyterian Church; and the John Kerr Memorial United Presbyterian Church in Polwarth Gardens is at present being constructed to his plans. Mr. Robertson also supplied the designs for the alterations on the Greenside parish church.

Mr. J. Coutts Michie has earned his Associateship not less on account of his merits as an artist than for the interest he has always taken in the promotion of art in Aberdeen, where he resides. Recently, largely owing to his exertions, the Aberdeen Art Society, which has now a membership of 400, was resuscitated, and the excellent exhibition which is at present being held in the art galleries promoted. He was also one of the leading spirits in the formation of the Scottish Artists' Society, and by his willingness to help others he has many friends. His artistic studies began at Edinburgh when he was fifteen years of age. He attended the School of Design under Mr. Hodder, gained a gold medal, and at nineteen entered the Academy's Life School, where he gained a scholarship at twenty-two. He subsequently went to Rome to study, and afterwards to Paris. Returning home, his health broke down, and he had to go to Tangier for six or seven years. His health

having been re-established, he has for the past few years been a steady exhibitor at Edinburgh, Glasgow and Aberdeen of portraits and landscapes. Quite recently he has painted on the East Lothian Tyne, and has produced works of great merit—imbued with a fine feeling for colour and pictorial effect. A landscape of much merit was his *Evening*, shown at the S.S.A. Exhibition last August, and now at Aberdeen; and one of the most complete works he has painted is *Autumn Clouds* (No. 91), which is on the line in the present R.S.A. Exhibition. He also shows in the Aberdeen Exhibition an excellent portrait of Lord Granville Gordon—brother of the Marquis of Huntly—and several Lothian landscapes of much beauty. His election will be very popular with the younger artists.

INIGO JONES AND OLD ST. PAUL'S.

THERE is some doubt as to the exact date of the commission for repairing St. Paul's. The work of restoration was, however, active in 1633, and proceeded without interruption till the great civil war. All writers concur in admitting that restoration was necessary, though few would allow that this was done in a way creditable to the genius of the architect. The cathedral, according to the unimpeachable testimony of Wren, was in a sad state of dilapidation and decay; indeed it does not appear that any material addition, or even repair, had been made since the days of Henry III. The houses of London, chiefly in those days composed of wood, and built as suited the fancy or the purse of the proprietors, were huddled close and built high, and the fresh air, the genial sun, and, what was properly worse in the eyes of the architect, a complete view of the church was little thought of. To give scope for improvement and secure a view of the cathedral to the citizens, who probably cared little about it, the removal of a number of houses was recommended, and armed with power Inigo cut away to his new work with less ceremony than many thought decorous. Some were offended at having a fireside, at which they and their ancestors had sat for generations, rudely shovelled away; others were enraged because the shop in which they carried on a lucrative trade was pulled down, and a "compensation" awarded, which they regarded rather as a contemptuous acknowledgment than even an imperfect repayment for the injury sustained; while a third class, and a much more numerous one, saw with no good-will the rebuilding of what all of them termed a steeple house, and, not a few, the "stronghold of Dagon;" the opposing of which they knew also might vex the king, and to add, if any addition could be imagined, to so great a crime as repairing a church, Laud, who was then Bishop of London, laid the first stone.

The demolition of many houses and the restoration of "Powles" were both bitterly remembered afterwards. In 1620, a commission was issued to the Archbishop of Canterbury, the Lord Chancellor, the Lord Mayor, the Lord Privy Seal, and many other distinguished personages, including Inigo Jones, surveyor to His Majesty's works, to inquire what repairs were necessary and what funds existed for carrying them into execution. A second commission was issued on April 10, 1631, in which the name of Inigo Jones does not appear. He was, however, says Britton, employed to superintend and direct the works, which were commenced in April, 1633.

The subscriptions collected for the repair of St. Paul's Cathedral are particularised in large vellum books, which are preserved. Sir William Dugdale has made copious extracts from them for his work. The total amount was 101,330*l.* 4*s.* 8*d.*, whereof only 35,551*l.* 2*s.* 4*d.* had been expended when the flames of civil discord put an end to all further progress in the works. The essential stimulus received, the repairs were begun in 1633; and Inigo Jones began to clear his way by destroying more than twenty houses which were built against the cathedral, with many other encroachments. He paled in the churchyard, and caused the sermons to be preached within the choir, instead of at the cross, for he was directed to begin at the south-east corner and proceed westward. When the architect dug the foundation for his portico, he found the earth in many places loose and unfit to sustain so great a weight. In some parts he turned arches, and in others the ground was rammed 2 feet in depth to remedy those defects. A great deal of old stone from the east end of the church was used in the basement. The pillars consisted of six stones each from the base to the capital, six pieces of ashlar for the lower parts of the columns, weighing 38 tons, and cost 26*s.* per ton. Nine capitals weighed 105 tons, and four architraves 38 tons, at 30*s.* per ton. Among the many other curious particulars, we learn from Malcolm that the carvers of the capital and enrichments had 3*s.* per day. Enoch Wyatt was employed sixteen days on the model of a vast statue for the north side (perhaps the pediment of the transept), for which he received 49*s.* 6*d.*, but it was never used.

The white marble was provided at Genoa by the direction of Sir William Curteine, Knt., and since his time

brought into England and delivered at the Tower Wharf by his son, William Curteine, at his own cost and charges, and by him freely given to be employed in the works of the west end of the cathedral of St. Paul's, in London. Zachary Taylor had 39*s.* 9*d.* for carving the patterns of the enrichments of the great marble door case, and for those of the lesser doors 13*s.* 6*d.*; they were after the designs of Inigo Jones. Nine years ran on in the prosecution of these repairs, and it was in contemplation to rebuild the pillars of the tower to obtain sufficient support for a stone spire. The scaffolds for this purpose were prepared, but the year 1642 produced events inimical to order, religion and domestic peace. All repairs ceased, and the accelerated ruin of St. Paul's commenced. The venerable cathedral became a stable and a barrack for dragoons, for soldiers had broken down the stalls, torn up the stones from the pavement and the monumental brasses from the stones, destroyed the tombs, dug saw-pits in the earth, and divided the spoils with the rending saw. Danger even seemed to have no terrors for these fanatics, who dared to remove the scaffolds and frames which supported the arches of the south transept; how they escaped when the stones fell is almost as wonderful as their folly. Strange as it may appear, while one part of this church was used in this manner, another received congregations for the purpose of praying and preaching; this was the east end and a part of the choir, separated by a brick wall; the congregation entered through one of the north windows converted to a door. The portico erected after a design of Inigo Jones met with treatment equally injurious, but profitable to the usurping inmates. Shops were built within it, and commodities sold by the tenants of every description. But that the monarchs who had endeavoured to restore St. Paul's might not behold those sacrilegious intrusions, even by their marble proxies on the balustrade, they were thrown down and demolished. In sad and sober prose, during the usurpation, the stately portico with the beautiful Corinthian pilasters being converted into shops for seamstresses and other trades, with lofts and stairs ascending thereto, the statues had been despitely thrown down and broken in pieces.

In the year 1639, Inigo Jones completed his repairs, including the beautiful though misapplied portico at the west end, which consisted of eight well-proportioned columns, those at the flanks being coupled with square insulated antæ. If the architect had taken the ancient design for a model he would have saved his memory much reproach. Unhappily, he aimed at improvement, and the consequence was a grand Corinthian portico, placed before a heterogeneous mass, plainer even than the Tuscan order. Jones made no alteration in the choir of St. Paul's; but in other parts, says Walpole, he made two capital faults: he first renewed the sides with very bad Gothic, and then added a Roman portico, magnificent and beautiful indeed, but which had no affinity with the ancient parts that remained, and made his own Gothic appear ten times heavier. Of this splendid mistake, this Grecian portico to a Gothic structure, there is a ground plan and elevation to scale in Kent's "Designs by Jones." The entire west front measures 161 feet long, and 162 feet from the ground to the top of the cross or tower, at each angle rises 140 feet, while over these ascends the central peak ornamented with pinnacles terminating in a cross and forming a screen to the end of the main roof of the building. The whole of this front is of the Corinthian order rusticated, and may be described as cumbrous in form but picturesque in effect. It is far otherwise with that noble portico to which the work described serves at once as a background and a contrast. This reaches in length 120 feet over the bases of the columns and rises 66 feet, measuring from the first step, of which there are five to the summit of the balustrade. There is no pediment, inasmuch as the picturesque rusticated peak performs in some degree the part of a pediment rising nearly 100 feet above the balustrade. There are in all fourteen fluted columns, of which eight stand in front and three on either side; nor are these last crowded, for the projection measures 42 feet. At each angle there is a square pilaster, proportioned and diminished, like its circular companions, with half pilasters to correspond where the portico unites with the wall. On the front line and on the return of these pilasters a column stands so close that the capitals and bases are all but touching; in the centre of the portico the space between the columns measures only 11 feet, while that which separates the others is only 9, thus giving air and access to the principal door. The columns including capitals and vases measure 46 feet high; on the parapet corresponding with each column a pedestal is inserted breaking forward and rising 9 inches above the cornice, serving at once as a blocking to the balusters and a support to a statue, of which the architect had designed ten, all princes and benefactors of the church. It was said there was nothing in this country so nobly proportioned and so simply splendid as this portico. The pilasters coupled to columns at each corner varied the sameness of the design and preserved the perpendicular profile of the angles, which the square projections above and below seemed to require, and which circular columns sacrifice.

BUILDERS' PLANS.

THE architects in the southern states of America have been protesting against the practice of erecting houses from plans which were prepared by builders. Mr. M. J. Dimmock, of Richmond, Virginia, in a paper on the subject says:—

The southern states in the past were strictly an agricultural district, and consequently the cities were few and the plantations large, and there was little which led to the study of architecture, and the buildings partook more of the practical than the artistic in design. There were public buildings and many planters' houses which were admirable in design and were planned to suit the wants and requirements of the day and climate, and some of these are to-day worthy of study.

But a new condition of affairs now exists, and the new South has become manufacturing as well as agricultural, and as a consequence her cities are growing and new towns have sprung into existence, and so new architectural conditions are required. The resources of the South are being rapidly developed, and capital from home and abroad is seeking investment. Great business schemes are projected, and it is a recognised fact that after maturing a scheme when the planning and erection of buildings is necessary, the first thing to be done by the projectors is to secure the professional services of an architect, one in whom all confidence is reposed, to advise with and prepare the plan, &c., of a building which shall fill all the requirements of the special scheme, not only as to arrangement of plan, but also as to appropriateness and beauty of design, and which shall not fall short, but surpass if possible, other buildings of a similar character. This is a recognised business procedure, and the only proper mode of carrying out the scheme in hand. Now to find this architect and adviser one must first look for an educated man in his profession, and one who has had experience in all matters pertaining thereto, and is able to study and solve the problem given him in a careful and businesslike manner in all its details, and the architect, to do this, must have years of study and long experience and a certain aptness for his profession, coupled with decision of character and a gentlemanly bearing, which are all necessary for success.

These qualifications it would be unreasonable to expect in a builder who has neither had the time nor means of study, and whose early manhood has been spent in the details of probably but one branch of the carpenter's trade. These men have, in some instances, familiarised themselves with a few plans and specifications prepared by architects, and have finally essayed the practice of architecture; and in most cases the community loses a good builder and gains a person too large in his own estimation for the honourable trade, and yet greatly too small for the profession he calls "Architecturing."

The trade of a builder is a most honourable one, and carries with it great responsibilities; and its emoluments are always satisfactory and often large; and there is always room in any community for a good builder while there should be no room for a pretender.

It would be impossible in this paper to enter into a criticism of the drawings furnished by builders, and to follow them up and examine the buildings erected from them; but suffice it to say, they are in almost every case crude, raw and undigested, and even to the uneducated eye there is something that stamps them as builders' drawings, and the house erected from them is neither in design a thing of beauty, nor in plan a joy for ever.

The question is how shall we seek to remedy this evil? The fault lay not at the door of the builder; for he, in making these so-called architectural designs, is but supplying a demand of the public, the masses who are too often ignorant and careless in all matters of architecture, and who, thinking to save the professional fee, will expend often twice the amount of this fee in patching up mistakes in faulty plans and specifications, and inflict on the community a Dolly Varden monstrosity.

We can only hope for an improvement by the gradual education of the public to a higher standard in architecture. That this standard is improving there is little doubt; and here in the South-land, which we all love so well, and in whose development we are peculiarly interested, there is a growing demand for better things, and the public is discriminating between good and bad architecture. This is the age of travel and observation, and much is learned by comparison. Art is now diffusing itself into everything, and this is seen in the simplest forms of household decoration; and the child of to-day is surrounded and educated by artistic objects that were not thought of in our boyhood days.

And so it behoves us now, one and all, to strive for this end, and with unceasing study and the careful preparation of every detail of design, both in small as in large buildings, to improve the architecture of the South, and to place it on a level with that of any other part of this land. Nature has been most

bountiful and the resources of our country are unlimited, and we desire the traveller in the future to pause and admire and study our architecture as well as our history.

Edinburgh Revisited.

SIR,—It is a strange feeling which is excited when one revisits, after a lapse of time, a city that once was familiar. Edinburgh is particularly adapted to move an architect when he renews acquaintance with it. Blessed with the finest sites in the world for building, and blessed with a liberal choice of the best stone for doing it, Edinburgh should stand first of all cities in the world for a magnificent display of architecture. Unhappily it does not. This regrettable fact may be owing partly to the lack of funds, or to that spirit of rigorous economy which seems to be inherent to the Scottish character, or to other causes.

The castle, the most prominent site, may be taken first. The more ancient portions to the south and east have been allowed to fall into lamentable decay, the whole skyline being now flattened down to a dreary stretch of slated roofs, without one redeeming feature to help it, and most of the ornamental details of the building itself being ruthlessly cut away in later alterations. A new block was erected at the north-east angle of this part about the year 1600 in the characteristic style of the period, but even here the roofs of the turrets have gone, and no effort has been made to restore them. What was done to the buildings generally in the past century has been of a contemptibly utilitarian character, as witness the factory-like block of barracks to the west, whilst the centre building in later years was recast by Mr. Billings in a "neither fish, flesh nor good red herring" style, quite unworthy of the author of the noble work on "Scottish Baronial Architecture." Of the modern buildings lately added to the castle, such as the principal gateway, all that can be said is that they might be worse, and, considering their official birth, they are fairly good of their kind.

It was left to a patriotic publisher of Edinburgh, the late Mr. Nelson (all honour to his memory), to bring back in a measure the ancient glories of the castle. He has restored the inner gate which stands prominently forward on the north. We have little left of ancient Scottish work of this sort to guide us in judging of the merits of the design, but it appears to be at least of good, vigorous and picturesque Mediæval character, and certainly shows well on that side of the castle. The gatehouse is in the form of a tower, the roadway passing through the lower portion, which has the usual vaulted archway, portcullis, &c., built by the Regent Morton. The top portion has now been restored with corbelled parapets and gabled gatehouse, this latter having two picturesque turrets corbelled out on the north side. It is perhaps unfortunate that the architect has faced this top portion with a tidy ashlar veneer, in startling contrast to the ancient substructure, which is of very coarse rubble-work, without even a string-course to break the continuity.

The old Parliament Hall has been also completely restored at Mr. Nelson's expense. The floors, which for 140 years cut the building up into hospital wards, have been removed, the fine old open timber roof exposed and restored, and the whole inside of the hall entirely overhauled and adorned with good wall panelling, covered with coats-of-arms and other appropriate ornament of a presumably Scottish character, and the great fireplace carried out after the manner usual in old Scottish castles.

For the rest this unequalled site is little better than a rough hill top. Where Mons Meg—Scotland's big gun—reposes the rock crops up in somewhat dangerous abruptness, much as it was left after the volcanic action which gave it birth thousands of years ago. The parapet in front of the old cannon is so low as to become dangerous, and is at best a mere commonplace wall without any effect. The adjoining chapel of St. Margaret's remains as to exterior as it was desecrated years ago by being turned into a gunpowder store; inside however it has been restored fairly enough, but in place of altar and suitable adjuncts one finds in possession a female vendor of photographs and guide-books, who cries her wares in rasping and unmelodious Doric. A great iron water-tank ramps up on the highest point of the rock in hideous utilitarian nakedness, whilst for a few pounds a stone tower of suitable character might be built round it, making an admirable finish to the whole surroundings. A plentiful growth of rank grass and weeds flourishing at its base, with a liberal distribution of sandwich wrappers and paper "pokes" whirling in the blast, make as dismal and as ill-kempt a termination as can well be conceived to the summit of the Royal Castle of Edinburgh.

Modern Gothic church architecture is still in a rather backward state in Scotland. Owing to the poverty of the Episcopal Church there are few efforts which will bear comparison with the enormous amount of church work in England. Of the churches of other denominations—notably the United Presbyterian—there is not much to be said. Even the vaunted General Assembly Hall woefully lacks the true ring of Gothic. It is stated by a reverend gentleman in a late book on St. Andrews that this semi-hall and church was designed by Pugin, but as the same divine also talks about the north transept of St. Andrews Cathedral looking down the South Street, which runs west to east, the statement must be taken with caution.

It is to old work we must look if we wish to study the Mediæval art of the North. No better restoration (in the truest meaning of the word) has yet been carried out than that of the old church of St. Giles. The architect has done what he had to do with admirable judgment, uncovering and judiciously patching up where needed, and generally doing enough and no more.

The whole inside was, up to late years, cut up into several different churches, all of which have now been cleared away, leaving the whole building displayed from west to east, with its side aisles and numerous quaint chapels, which show much that is both graceful and curious in various patterns of vaulting, quaint carving and picturesque detail generally. The exterior of the church went through a terrible handling by the late Mr. Burn many years ago, and was left by him a polished ashlar Batty-Langley abomination, with all its antiquity wrenched out of it, and save for the imperial-crowned spire, which happily escaped his ruthless touch, the church outside might be a building of, say, sixty years ago. Whilst giving the architect of the late restorations all the credit he merits, it must be added that much is to be desired in the new portions which he has inserted of a paltry character; they are quite out of keeping with the sturdiness of the old work. This is notably seen in the screen across the north transept, which is of a cold slatey-blue stone, the details of which are too ornate, and the openings are filled in with plate-glass. It is to be regretted that the architect did not follow the existing details of the old screen; ample remains, if I mistake not, being still to be seen. The pulpit, too, is carried out in a similar ornate style, as also the west porch, which is terminated with three insignificant pediments, filled in with rows of miserably little and intensely modern figures of Scottish kings and provincial saints, all carved in a cast-iron manner, emulating the metal-work on the adjacent monument to the Duke of Buccleuch. Most of the windows have been filled in with painted-glass, in which a dark brown colour unpleasantly predominates. It seems as if the designer, in his anxiety to avoid the garishness of the Glasgow cathedral glass, had run into the opposite extreme of almost obscuring the whole colour in this unhappy manner. He might have done something to impart an effect of breadth to the mullions and other window divisions, which in the Burn spoliation had been thinned down by at least a third of their former thickness. The great west window shows a wonderful row of prophets, priests and kings, standing at attention in massive line, displaying butcher-like biceps, with great flowing beards, red and unkempt; and were it not for their orthodox raiment they might be taken for a posse of gillies fresh from the mountains further north. A monument of very graceful Jacobean has been lately erected to the memory of the great Earl of Montrose, but with Scotch exactitude it has been pushed up into a small and dark chapel—his reputed burying-place—where its beautiful details cannot be properly appreciated. One would have thought that a site in the adjacent south aisle would have been sufficiently near to the traditional “lair” of the murdered patriot to have satisfied even a Caledonian vestry.

Of the new buildings the University schools take the first rank. They are of an Italianesque design, well planned and quite unlike anything else in the town, or indeed in Great Britain. The work is full of delicate and good carved details, intermixed with solid and substantial wall-spaces, but the outline is not as picturesque as was desirable. The new dome upon the College buildings is uninteresting. The building for the National Portrait Gallery in Queen Street is in a mixture of French and Venetian Gothic, clever and picturesque in design, but rising as it does sheer out of the pavement its architectural effect is marred. It has bold corbelled corner turrets and good details, but the inside seems strangely dark for the professed purposes of the building.

Mr. Sidney Mitchell shares with Dr. Anderson the architectural honours of the North. He is a very truthful exponent of the national style in which corbelled turrets, circular stair towers and crow steps are so conspicuous and picturesque features, and some buildings which he has carried out in the village of the Water of Leith do him and the style much credit, which is more than can be said of most of the modern Scotch baronial work in the North. He has lately rebuilt the Market Cross, but it is to be regretted that he has stuck so

faithfully to the original design, handed down by poor engravings, which are bald and uninteresting.

St. John's and St. Paul's Episcopal Churches have been enlarged, and in both the original details have been reproduced with a fidelity that is too faithful. The cathedral of the Scottish Episcopal Church is the best specimen of modern Gothic in Edinburgh. It stands, unhappily, at the end of one of the gloomiest and most depressingly Classic streets in the town. The cathedral, which is unfinished, is from the designs of Sir Gilbert Scott, and is not to be compared even to many of his less ambitious works, either in point of design or elegance of execution. The central tower is stumpy and heavy, and there is a want of picturesqueness everywhere. As to the acres of new streets, squares and crescents which have been in latter years built in the west end of the town, little need be said. One can only regret the chances that have been thrown away of making this newer town a thing of real beauty, worthy of a country where such advantages have been so profusely provided. The one prevailing idea is bow windows, which multiply themselves interminably in wearisome persistency. What a contrast they offer to the beautiful buildings on the Cadogan estate and other parts of London.—Yours obediently,
SCOTUS.

Impney, Droitwich.

SIR,—With reference to the illustration of Impney, Droitwich, in your last issue, I shall be obliged if you will inform me *what additions by Mr. J. R. Nicholls, architect, are shown in the phototype?* There is absolutely nothing there but that which was carried out twelve years ago by M. Tronquois, of Paris, and myself.—I am, yours obediently,
R. PHENÉ SPIERS.

Carlton Chambers, 12 Regent Street:

April 1.

[The additions referred to are mainly confined to the interior.—ED.]

GENERAL.

The Paris Municipality have unanimously decided that the Exhibition of 1900 is to be held in the Champ de Mars.

Mr. John Bartholomew, of Edinburgh, many of whose maps and plans were works of art, died in London on March 31. He was born in 1831, and received his first instruction in cartography from his father.

A Fine Art and Industrial Exhibition was opened at Redditch on Monday, in the expectation that sufficient money would be obtained to pay off the small debt on the local art school.

The Bradford Historical and Antiquarian Society have arranged to pay a visit to Kirkstall and Adel in the following month of May.

Mr. Henry Ough, of the firm of Henry Ough & Son, of 84 St. Paul's Churchyard, E.C., has been appointed one of the diocesan surveyors of St. Albans diocese, under the Ecclesiastical Dilapidations Act, 1871.

Messrs. New & Son, of 62 George Street, Portman Square, have been engaged by the guardians of Paddington parish to prepare plans for a new kitchen and lunacy wards at the workhouse in the Harrow Road.

The Restoration of the west front of Rochester Cathedral, under the direction of the cathedral architect, Mr. J. L. Pearson, R.A., is estimated to cost between 6,000*l.* and 7,000*l.*

Mr. H. F. Gullan will read a paper entitled “The Limestone Bed and Road-cutting in Northamptonshire” at the meeting of the Liverpool Architectural Society, on Monday, April 10.

The Competition Designs for new offices for the County Council of the West Riding of Yorkshire will be on view at the Corn Exchange, Wakefield, on Wednesday next, 12th inst., for the Press at 2 o'clock and for the general public from 3 to 5 o'clock.

In the Competition for the new orphanage for the British Columbia Protestant Orphans' Home, Mr. Thomas Hooper has been placed first. Mr. Hooper will carry out the work, the second and third competitors, Mr. T. C. Forby and Messrs. Soule & Day receiving premiums of 100*l.* and 50*l.* respectively. Thirteen sets of plans, based on sketches and suggestions furnished to the committee by Mr. R. Owen Allsop, were received. Mr. R. M. Fripp, F.R.I.B.A., assisted the committee in the selection of the plans. Tenders will be at once invited for the work according to the plans of the successful competitor. The new building will be a great boon to Victoria, where the present accommodation for orphans is very limited.

Mr. Lewis F. Day will deliver a lecture entitled “Some Masters of Ornament” (Cantor lecture) at the meeting of the Society of Arts, on Monday, the 10th inst.

The Architect.

THE WEEK.

THE majority of the London County Council were so satisfied with their own wisdom and the strong hold they thought they had on the affections of Londoners that they despised warnings from whatever side they came. The late defeat of the Progressive candidate for election at Clapham ought to instruct them of what will be their fate at the next general election of members for the County Council. The public, no doubt, are unwilling to cashier their representatives without giving them time to show whether they will correct errors of judgment or not. A more significant hint than usual has now been given to the Council, leaving them a choice of two alternatives, viz. to amend their ways or prepare to be in the minority at the next elections.

It is little less than ominous that simultaneously with the hint thus given to the County Council an announcement is published that for purposes of revenue the rateage in the pound is to be increased, with the prospect of being still further increased in succeeding years. The abolition of the coal and wine dues was considered a master stroke of policy. Outside the Council, however, it is now generally known as having injured Londoners without the slightest return as a set off. It may be added that coals have been dearer, and wine not a penny a bottle the cheaper since. We think that candidates for election for the next Council could not do better than undertake to, if possible, re-establish this source of revenue, which has paid for so vast improvements in the past and at the same time has not been felt either by coal and wine merchants or coal and wine consumers.

ON Wednesday there was a meeting of the County Council of the West Riding of Yorkshire, when the awarding of premiums for designs for the new county offices at Wakefield was considered. The chairman of the General Purposes Committee proposed that the first prize of 200*l.* should be given to the authors of plans No. 3 (Messrs. GIBSON & RUSSELL, Little Queen Street, Westminster); that the second prize of 100*l.* be given to the authors of plans No. 19 (Messrs. COCKSEY & COX, Craven Street, Strand, London), and the third prize of 50*l.*, to the authors of plans No. 28 (Messrs. SIMPSON & RICHARDSON, of Wakefield). The proposal was adopted. It was stated that none of the selected designs could be carried out for 42,000*l.* The estimates of the competitors varied from 38,000*l.* to 130,000*l.* It was proposed to communicate with the authors of the first design, and obtain if possible some modifications in order to reduce the estimates, which, it is understood, amounted to 64,000*l.* The *Leeds Mercury* says that the opinion was almost universal that the plans of Messrs. GIBSON & RUSSELL, which have taken the first prize, were the most satisfactory. The various elevations are striking, attractive and ornamental, but the great charm lies in the manner in which the building has been planned. Speaking of the design generally, it may be said to be in the Victorian Renaissance style—thoroughly modern. The disposal of the various offices required has been carried out on the corridor principle, which may be somewhat old-fashioned, but which nevertheless possesses many advantages.

It will be absurd for Corporations to expect that they can obtain efficient teachers of technical subjects for the wages of copying-clerks. On Wednesday the Technical Instruction Committee of the Manchester City Council proposed that the following teachers should obtain an increase of salary:—Mr. H. G. JORDAN, chief lecturer on engineering, from 300*l.* to 350*l.* per annum; Mr. T. W. FOX, chief lecturer on textiles, from 250*l.* to 300*l.* per annum; Mr. R. TRAINOR, instructor in woodworking, from 200*l.* to 225*l.* per annum; Mr. W. H. DAVIES, practical instructor in engineering, from 185*l.* to 200*l.* per annum; and Mr. S. JOYCE, second lecturer on electrical engineering, from 150*l.* to 200*l.* per annum. The salaries are not extrava-

gant for gentlemen who occupy onerous positions, but no less than twenty-three members of the Corporation opposed the proposals. Fortunately there were thirty-nine members who were in favour of the increase, and it was sanctioned. It is quite possible to obtain plenty of teachers bearing the South Kensington stamp who are not worth a hundred a year, but Manchester cannot be eager to have its students bewildered by such men.

WARS and rumours of war have lately been the order of the day in the industrial world. The trade dispute in America, which would have militated against the interests of the world's exhibitors at the forthcoming show at Chicago, has fortunately been averted. In Australia difficulties have arisen in regard of one of the most important of the staple trades. In England we cannot boast that we are free from trouble. Any person who has taken the opportunity to glance over the information given in our daily newspapers of what is occurring in all parts of the world must be now aware that it is easier to paralyse trade and industry than to better the condition of working men. Trades unions arose ostensibly to secure that justice was done to operatives without infringing the rights of employers. Unfortunately too many of those charged with conducting the work of trades unions and like associations are not logicians, and they have not advanced the interests of those they thought they were promoting. The result, that they have secured a competency for themselves, cannot be considered satisfactory, when it has been earned at the expense of the operatives and masters alike. We are not without hopes that these evils are beginning to be realised, and that in due time a more rational and beneficial course will be adopted by those interested, or who suppose they are interested, in promoting the welfare of the working classes. If more wisdom does not guide the advisers of operatives, it will be only a question of time, for in the end business and capital will be driven out of the country; but then also will come an end to the business of these speculative traders on their own fellows. So far they have only succeeded in verifying the old fable, that those who kill the goose can expect no more golden eggs.

A SOCIETY has been formed under the title of "The National Society for Checking Abuses of Public Advertising." The objects of the Society, however, do not aim at preventing advertising, as it is generally understood. Whatever the profession or trade persons may have adopted, those engaged in the same never are supposed to "talk shop" out of business hours—at any rate, it is bad taste, according to unwritten laws, to do so. There is no doubt that it was most needful that some steps should be taken in order to prevent an intrusion which threatens to deprive business people of the chance of forgetting business and "the shop" in their time of leisure, and while endeavouring to enjoy a holiday in country scenes. The whole interest of some beautiful natural scenery is too often now marred by huge advertising boards, recalling to the mind of the business man that it is pills that he requires rather than the beauties of nature. A most influential body of men have already joined the Society as members, and among them will be found the names of eminent architects, artists, and other professions. We wish the Society all success.

A COLLECTION of reproductions of chimneypieces that were manufactured by Mr. F. A. FAWKES, of Chelmsford, has been published by Mr. BATSFORD. Like all the work that comes from Mr. FAWKES'S workshops, the chimneypieces are refined in style, and the details will bear the keenest scrutiny. They are specially adapted for the style of building which is now in favour, and it may be said that some of the chimneypieces will sustain a comparison with the best work of the eighteenth century.

THE following jurors have been elected for the section of architecture in this year's Salon:—MM. COQUART, 119 votes; PASCAL, 115; GARNIER, 114; GUADET, 104; MAYEUX, 102; GINAIN, 97; LOVIOT, 93; VAUDREMER, 86; RAULIN, 83; DAUMET, 78; CORROYER, 68; LALOUX, 64. Supplementary members:—MM. NORMAND, 55 votes; GUILLAUME, 54.

DERBYSHIRE, DEVONSHIRE AND DORSETSHIRE.*

IN our time country folks find everyday life is too serious an affair to be neglected, and in consequence the race of village and district archæologists is dying out. The few who still survive are likely to be finished off by parish councils and other newly-devised institutions. It is with a sort of envy we look back to the Arcadian days when simple people awoke to the interest of the "curiosities" in their villages, and lost no time in communicating their discoveries to the *Gentleman's Magazine* and other respectable repositories of erudition. Men were then easily pleased, and anybody who was lucky in finding a coin or an old shoe, or who was able to point to a feature in his parish church as an illustration of somebody's communication in a previous number, might well feel that since he was adding to the stock of their information he was a benefactor of the public. It is a pleasant task, therefore, to have to go through the pages in which Mr. GOMME has enshrined the most characteristic of one class of these old communications. They are all inspired by the simplest and honestest desire to do something toward sustaining an interest in the relics of the past. The writers may not have been scientific or systematic, but even when they are incorrect we must forgive them on account of their good-will towards antiquity. Their acceptance of improbabilities testifies to the simplicity of their belief in other matters.

The three counties which are treated in the latest volume are Derbyshire, Devonshire and Dorsetshire. The first has had to grow with the times, and has become as modern as most of its neighbours. But the Devonshire and Dorsetshire of to-day, if they have lost the rusticity of the last century and of the early part of the nineteenth, are still admittedly behind the rest of England in many things. If the inhabitants of the two counties could be induced to take some interest in archæological subjects their communications would not be unlike those which were received by Mr. URBAN many years ago. As the contents of the volumes are necessarily disconnected, we fear our notice must assume a similar character.

Derbyshire has famous houses, and among the most remarkable is Chatsworth, which is also the costliest to uphold. It appears from one of the communications that the waterworks were originally constructed by GUILLET, a Frenchman, in 1690, and it was probably a desire to outdo them which inspired PAXTON when he planned the Sydenham fountains. The hall of Kedleston House, designed by the Brothers ADAM about 1765, contains "twenty Corinthian columns of veined alabaster, 25 feet high, brought from Lord CURZON's quarries at Red Hill, in Nottinghamshire." Haddon Hall in 1794 was in a very ruinous condition, nobody inhabiting it. A correspondent, in sending a sketch of Hardwicke Hall, expresses the character of the building briefly:—"Hardwicke was built in the reign of Queen ELIZABETH, and possesses all the features of sublimity that we attach to the fanciful and well-painted edifices of our best romances." Another correspondent, writing in 1792, takes a philosophic view of the incongruities which were then common in church architecture. Describing Mackworth Church, he says, "We could observe a very handsome chancel, lately repaired and decorated by Grecian architecture; a little *malà propos*, you will allow, connected with a light Gothic window. However, it is better so than damp, ragged and unwholesome, as too many village churches are." As late as 1822 there stood between Ashbourne and Derby a chapel of the Established Church known as "Halter Devil Chapel." The belief was that a man named BROWN "went to catch his horse, when he by some means caught the devil, who broke loose and vanished in a flash of fire." To commemorate his escape, BROWN built the chapel, and endowed it with property worth 12*l.* a year. An inscription on the church recorded its origin. The twisted spire of Chesterfield Church does not appear to have caused much inquiry into its cause. One correspondent says of it:—"The spire is of timber, and, from a strange fancy of the architect, crooked; the angular flutings,

if I may be allowed the term, wind spirally from the base to the top, and are covered with lead." The old monuments in the church were neglected. We read of one that "has been covered with undisturbed dust, mats and pews for many years, except at distant intervals; the curious traveller or hardy antiquary thrusts his adventurous face close upon it, in defiance of kneeling cushions, ragged boards and crooked nails." Insult was added to injury on one mailed figure, for "the person's head appears to have been shot off entirely from the mouth upwards, and the helmet replaced lightly on the remaining part." Another correspondent who endeavoured to suggest the character of the mutilated figure wrote:—"Surely no artist could have erred so egregiously as to have replaced a broken head in a manner so totally out of nature. As some chiselling was necessary to fit on the new one, what could have been his motive for leaving the old chin? Possibly some modern restorer, imitating his predecessor, may furnish him with a pair of old feet in place of the absent hands." So weird and unpleasant an appearance could hardly be the result of accident, and probably was the practical joke of some unprincipled stonecutter. Another instance may be cited. A Mr. MALCOLM, writing in 1794 about Shirland Church, refers to a figure that was placed under an "uncommonly elegant Gothic arch." This monument, he says, "is another instance of the abominable license permitted to clowns in country churches. One would almost suppose that this unfortunate knight had been mistaken for the decayed representation of their tutelar saint; they have so carefully picked him to pieces, supposing his fragments to possess supernatural qualities." A short time before the correspondent wrote, a large beam fell down over the singing gallery in Shirland Church; it should have come in contact with the vandals, or rather with the officers, of the church who tolerated the mischief.

In Devonshire, also, orthodoxy was enabled to assert its earnestness by destroying ancient work, with at least the tolerance, if not the approval, of the clergy and churchwardens. One of the correspondents of Mr. URBAN, in a tone of sorrow and anger, writes:—"Elsewhere the hand of depredation and destruction only partially fixes its hateful impress on the works of ancient art and magnificence; but here everything that is venerable for its antiquity, or beautiful for its material and workmanship, is subject to malicious injury. The spoliage has been committed in some of the most extensive ecclesiastical buildings in various parts of the county is unlimited. It is impossible to view, without indignation, so many of its once noble and highly adorned churches savagely despoiled of every graceful and ornamental feature under the plea, perhaps, of necessity or convenience. But what excuse can be proffered or accepted for mischief perpetrated for its own sake, permitted by negligence, encouraged by parsimony, or, for the reverse is sometimes alleged in extenuation of the offence, effected by prodigality?" It should not be forgotten that this indictment against the Devonshire clergy, for of course they were the real offenders, is dated as late as 1834, and hence it may be assumed that all that had been done up to that time was not sufficient to satisfy their aversion to the beautiful work of an earlier age.

In some of the examples cited it might be supposed that the terror inspired by remains of antiquity had overcome men's reason. The beautiful sepulchral chapel of Sir JOHN SPEKE in Exeter Cathedral was converted into a public thoroughfare. At Barnstaple there were three aisles, which became displeasing to the eyes of the men who were supposed to be the guardians of the building, whereupon "the arches and pillars which sustained the triple roof have been entirely demolished, and with these every vestige of antiquity which the interior contained, save only the huge tower in the centre of the south aisle, which was left for want of means to destroy its massy walls." At Bideford the clergy granted one concession, for, instead of destroying the clustered pillars, they "have removed them into the churchyard, where they serve as gateposts before the porch of the temple to which in better days they belonged." There was a rooted aversion to tracery, and of course it received scant mercy; consequently, says a correspondent, "the windows of very few of the churches exhibit anything more than a row of yawning apertures." In another place he regretfully remarks how "the same hands which at one

* *The Gentleman's Magazine Library*. Edited by G. L. Gomme, F.S.A.: English Topography. Part III. (Derbyshire—Dorsetshire.) London: Elliot Stock.

time are employed in squandering money and torturing materials into the ugliest of forms, are at another perhaps not very distant period engaged in the destruction of an ancient church or a curious domestic building, thus exterminating the models of ancient architecture, which ought to be spared and protected as furnishing the standard of the Pointed style."

It is needless to say that so important a county as Devonshire furnished subjects for many notes which still have interest for the archæologist. One relates to the chapel which used to stand on a bridge of Exeter. Owing, we suppose, to a settlement, a crack appeared in one of the walls, and "the protecting genius of the church would exclaim, 'Repair, but not destroy!' but this small, still voice would be drowned in the yells of the demon of improvement." As a rule Exeter is not credited with the possession of a desire to improve, but sixty years ago the city may have wished for changes. At any rate St. Edmund's on the Bridge was demolished about the year 1835. It was a red sandstone building, parts of which, at least, dated from the thirteenth century. These consisted of a nave and side aisle; there were also galleries which appear to have been erected in the reign of JAMES I. The font was modern; it "resembled an apothecary's mortar, and when not used was drawn up by pulleys to the bressummer of the west gallery."

A communication from Awliscombe explains the kind of tithes which were exacted in that parish, viz. for every cow giving milk 4d., for every calf 4d., for the foal of every mare 1d.; for every hogshead of cider 4d., for every herb garden 1d., for every acre mown 4d., for every lamb 4d., for every fleece of wool 2d., for every pig 2d., a hearth 1d., honey and geese in kind. The clerk was paid 2l. 12s. a year and the sexton 1l. 3s. In the church of Clyst St. George "the corbels which terminate the hood-mouldings of the large west window of the tower, though very roughly carved, clearly represent, one, a female with a horned head-dress, and reticulated jewelled crespine enclosing the hair; and the other, a Saracen, with turban and moustache." The tower was erected between 1460 and 1481, and the writer asks, "What had we to do with the Saracens at that period?" At Ford Abbey there was an auction held in 1846, and among the lots were "five pieces of Arras tapestry, after the cartoons of RAPHAEL, presented by Queen ANNE to Mr. Secretary GWYN, and for which his son refused 30,000l. offered by Count ORLOFF on behalf of the Empress CATHARINE of Russia." They were bought by the new proprietor of Ford Abbey for 2,200l. Among the places described is Hayes Wood, the birthplace of Sir WALTER RALEIGH. It is a brick edifice, one storey in height, with a long garden in front. The room in which he was born is pleasant, commanding a view of the garden and the romantic scenery around. RALEIGH wished to purchase it, for, as he said, "From the natural disposition I have to the place, being born in that house, I had rather seat myself there than anywhere else," but the proprietor declined to sell.

There is a long history of Tavistock Abbey which, since the Reformation, is associated with the BEDFORD family. It was surrendered in 1538; the abbot obtained the very large pension of 100l. a year, the prior obtained one of 10l., the monks from 6l. to 5l. 6s. 8d., and novices 2l. a year. The abbey church stood until about 1670. It was a noble building about 350 feet in length; the chapter-house and Saxon school were demolished in 1736, in order that the site might be used to build a residence for the Duke of BEDFORD's steward. A Saxon school existed in other places besides Tavistock, for according to Archbishop PARKER, as many of the early charters and monuments were written in the Saxon tongue, such schools were provided in order to continue the language from age to age, lest it should become obsolete. The abbey was one of the earliest to possess a printing-press, and a translation of the "Consolations" of BOETHIUS was issued from it in 1524.

There are extracts given from the churchwardens' accounts for the church of St. Eustace, Tavistock. Among these are charges for collecting rushes for strewing the church before festivals, for sending a man and horse to Plymouth to buy wax to make candles, for repairing windows and painting figures on them, for drinkings to the workmen, and so on. At a later time we read of 8s. being

paid for killing eight foxes, and 9d. for a chain to fasten the "dictionarie" in the schoolhouse.

The communications from Dorsetshire do not display the interest in the preservation of churches which marks those from other counties. We must imagine either that few misdeeds were to be recorded or that the correspondents were indifferent, and the latter supposition is the more probable. There are two churches which have secured attention, viz. Sherborne and Wimborne. Sherborne Collegiate Church or Minster was at one time a cathedral. It was nearly all destroyed by fire in 1436, when the building was the scene of a row which arose out of a desire on the part of the inhabitants to assert their privileges. The body of the abbey was used as a parish church, but the townsmen afterwards set up a claim on a chapel known as All Hallows, which was to be employed as a baptistery, and they placed a font there. The monks objected. In one of the altercations "a shaft with fier" was shot into a partition that divided the monks from the laymen, and a fire took place which caused great destruction. The columns and arches supporting the tower and the gallery round the lantern are parts of the Norman work that have survived.

There is a tradition that ALFRED designed a church at Wimborne, where his brother ÆTHELRED was buried. The condition into which the building that has so legendary a history had fallen in 1800 may be judged from the following extract: "Within the church the eye is gratified with decent whitewash and regular pews; though the information about the churchwardens who presided at that improvement had been more fitly preserved in the parish register than written over the centre arch of the church; such pitiful ostentation violates the general aspect of antiquity. The organ appears modern, and in size well adapted to the church. Its west front has much finery, and that towards the choir was never surpassed in tawdry-decoration by a gingerbread watch. It has a disgusting effect."

We have said enough, we trust, to suggest the courage which was so often exhibited in gloomy days by the correspondents of the *Gentleman's Magazine*. The critics would no doubt be often puzzled to explain the grounds on which they condemned the operations they saw in progress. But they knew that what was being perpetrated would diminish the value of the old buildings, and on that account they attacked all who had a share in it. There is much else in Mr. GOMME's selections which will be interesting to our readers, and the volumes will form a valuable work of reference for everyone who has an interest in English buildings.

CONDITIONS OF FORESTRY AS A BUSINESS.*

FORESTRY is a business, like agriculture—an industry which is concerned in the production of a soil crop. It is the art of managing a wood crop so that it will make the best harvest of timber in the shortest time at the greatest profit. Forestry differs from agriculture, however, in that it takes many years for the crop to mature, and the crop is then a complicated one. Forestry in the United States as a defined business is now in its earliest stages—chaotic and undeveloped. In its most perfect conditions forestry is not a single science or art, but combines relations to several sciences and arts. On its scientific side it touches botany, chemistry, geology, meteorology, physics, geography and entomology; on the art side it touches horticulture, arboriculture, lumbering and protection from fires.

In parts of Europe the growth of timber is already well systematised, but knowledge of the subject in all its details has been of slow growth. More than a hundred years ago a few alarmists in Europe prophesied an approaching dearth of timber. This agitation helped to induce economy in the use of timber, and to delay the evils predicted. Without giving the strictest attention to systematic arrangement, we may note some of the chief attainments by the leading countries of Europe in the management of forests, and the methods adopted to accomplish such results.

It would seem that Government ownership and control of much of the forests in the old country gave a great advantage over our newer country, where "private enterprise" accomplishes almost everything. There even the woodlands of corporations and of individuals are subject to the laws of the

* A paper contributed to the *Engineering Magazine*, New York, by Mr. J. Beal, M.S., Ph.D.

country, which specify how much may be cut in each year. These laws are enforced by officials well educated for the business. Forests are systematically inspected, and reports made concerning their condition and needs. The inspector acts as "a paternal adviser" to all owners of forests. In the words of a recent American consul to Austria-Hungary:—"The owner of forest land in Austria must exercise extraordinary care not to be guilty of trespass upon his own lands." How different the feeling of owners of land in the United States. In the country above referred to the array of forest officials of various grades maintained numbers nearly 32,000 persons. In all of these particulars the fact must not be lost sight of that wages are much lower and interest on investments much less remunerative than in the United States.

The large number of officials who must pass rigid examination makes it possible and even necessary to maintain numerous schools to keep up a supply of skilled men. The encouragement of profitable employment induces pupils to patronise the schools, which give laboratory or practical work, often in the forests, as well as lectures in the classroom. To some extent these subjects are taught in other schools than those for the special object of educating foresters. These officials usually serve for life, and are pensioned in old age or in case of disability.

By dint of great energy of a few persons in this country attention has been called to the greed and dishonesty of men who steal timber from the public lands and to the evil effects of removing vegetation from mountain slopes. Many instances of the same kind have been enumerated in Europe, where the evil effects remain as a warning to newer countries. The cost of reclaiming some of these waste places has been great. In this reclamation seeds from the scattering trees cannot be relied on to furnish seedlings for the new growth, but nursery-grown stock must be well set and afterwards properly cared for. Experience has led to the formation of many rules in relation to forest management. For example, on sandy soil and on steep mountain slopes timber can only be cut in narrow strips or thinned out. Grazing among timber is never permitted. Stringent rules in regard to igniting fires in or near forests are enforced.

Between 1860 and 1887 France reforested over 250,000 acres of mountain lands at a cost of 30,000,000 dols., the State paying one-half. In 1887 the total annual appropriation for the forestry department of France was 5,000,000 dols. Here the people of the United States may well take warning. How much more economical it would be to spend a little money now in preventing devastation than to suffer the consequences for a time and then possibly spend enormous sums in restoring the forests to the mountain slopes.

In Germany about 25 per cent. of the entire area is devoted to forests. Of this amount about 32 per cent. is Government land, 15 per cent. belongs to communities, 1.3 per cent. belongs to charitable and other institutions, 2 per cent. belongs to corporations and 48 per cent. belongs to private parties. Without the supervision of state officials "a reckless devastation of forests would be the consequence," just the condition we are experiencing in most regions of our own free country. In the Eiffel district the mountain slopes were reforested and otherwise improved at the expense of the Government, though much of the land belonged to communities.

A chief director of forests in Germany, in writing to a United States consul, says:—"You are certainly quite right when you speak of the importance of forest culture for the United States, but allow me to express my belief that no earnest work in that direction will be accomplished there. The culture of the forests proceeds too slowly to suit your countrymen, and the profits are not forthcoming soon enough. In my opinion good results from forest culture can only be had in the United States when the Government shall have taken the matter into its own hands." Dr. Otto von Hagen says:—"The forest is a trust handed down to us from past ages, whose value consists not alone in the income derived from wood, but also in the importance which it exerts through its influence on climate and rainfall or land culture. Its importance is not merely a question of the present day or of the present ownership, but is also a matter which concerns the future welfare of the people." For these and other reasons it has been determined that it is a duty to interfere by legislation with the waste of timber.

Think of the time required to grow trees of certain species fit to cut for important purposes. In Germany the age for cutting oaks is 150 to 180 years; beech, 100 to 120 years; Scotch fir or birch, 30 to 100 years; though for some purposes, of course, trees are cut when much younger. One of our consuls to France in 1887 observed that "forests are much more easily destroyed than replaced, for in three years, from 1788 to 1791, almost as large an area in France was deforested as has been reforested in the last ninety years, although much attention has been paid to the subject during this time."

The older and more thickly-settled countries of Europe have all passed through the stage in which many of our states have but recently passed or are now passing. Their land in most instances was well covered with forests. They cut and fired

and wasted as we are doing, and have long been aware of many of the evil effects of this practice. To what extent shall we learn and profit by their mistakes?

Under the circumstances what can the people of the United States accomplish? In what ways can we best secure a reform in forest management? Legislation, whether state or federal, will accomplish little, until there are enough stalwart persons thoroughly interested to continue under adverse conditions to work for the success of a better management of lands in forests or lands which ought to be covered with forests. Something may be done by forest commissions, but too much is likely to be expected of them, and to save expense somebody will advocate their abolition—and somebody sooner or later will succeed. The value of forestry commissions consists chiefly in giving advice and in educating the people.

Tree-planting on a large and expensive scale is not likely soon to be so skilfully conducted that satisfactory profits will be apparent. But notwithstanding, trees of every kind should be planted in many places, and the sooner the better for us all. Probably not one in a thousand now knows enough about the subject to proceed intelligently to take the best care of his forest or to reclothe land with timber in the most economical manner. Those who try the experiment should be able to wait.

Over a hundred years ago some persons in Europe were foolish (?) enough to plant a few white pines from North America. In the language of our time they would be known as "cranks," and yet who shall dare place a sufficiently high estimate on the value of that simple experiment, for it has demonstrated that our white pine is one of the best of trees to grow for timber in that country? We need men in every county of every state who will have enthusiasm and foresight enough to plant a few trees in places where there may be a prospect for growth a long time without molestation. Before these experiments are completed there will be many anxiously waiting to profit by the results.

We live in a comparatively new country, where our fathers and grandfathers cut down and burned the finest of trees to make room for crops and pasture. We have been taught to destroy trees and not to save them—much less to replant. The arguments for preserving the virgin forests of a new country are by no means all on one side, and no one should expect the trees to be preserved. In most cases the profits of holding are too small to pay for the investment.

Michigan once had about 150,000,000,000 feet (board measure) of standing pine, which was believed to be well-nigh inexhaustible. Those now living find remaining only comparatively small tracks in the back counties. Even with what might be considered good management in a thinly inhabited country, where lumber was cheap, it was soon found next to impossible to preserve this timber, however much the owners might desire to do so. In many seasons the fires destroyed as much pine as the woodman's axe. Dead pines must be cut to save them, and the *débris* was almost sure to burn and the fire to spread to the standing trees. To some extent the same condition of things prevails with regard to the "hardwood" trees, though in most cases these are not so likely to be destroyed by fire. In a business way there are men now spending much time and money in defending their remaining pine lands from fire. But more system is needed, and the care should be more general than it ever has been.

The study of European methods and results in forestry by competent men is not enough, says one writer.* It is not even the most important thing for us. Nothing can be very useful to us which is not based upon careful study of the conditions peculiar to this country. We must have in time a system of American forestry if we are to avoid serious disasters to our national interests and civilisation. The forestry of this country must be the product of growth, which has as yet scarcely begun. It will be developed by continued and widespread observation, and by constant comparison of the results of practice. It is necessary to remind ourselves that no useful system of forest management can be originated or created by legislative enactment. There must be special knowledge and national good sense regarding the needs of this country behind forestry laws, or they will be useless and mischievous.

It is important to understand the value of great areas of growing trees on the surrounding cultivated land, and to know in what respect they check fierce winds, prevent rapid evaporation of moisture, or encourage late frosts in spring. But the possession of this knowledge is not likely to induce men to save trees or to plant trees for the benefit of persons owning farms in the surrounding townships or in other counties. Here is one of the best of reasons why the state and nation should take an active part in the management of forests.

It is difficult to induce most persons to understand fully the results of a timber famine. They have heard more or less of this talk for years, but they believe the day is yet far distant when our people will suffer much inconvenience from lack of timber. They argue that, as timber becomes scarce and more

* "Garden and Forest," vol. i, p. 26.

expensive, less of it will be used. We shall burn coal for fuel, and use more iron and steel. Transportation will be cheaper, and timber can be transported for long distances. The use of the land to produce various grains, grasses, fruits and vegetables will help to pay higher prices for timber.

In the moister portions of our country, when the original forests were cleared away, seedlings and sprouts in immense quantities sprang up to contend for every foot of available space. In cutting away the valuable timber there are usually large numbers of "young things" up to 6 inches or more in diameter which, if protected from fire and other destroyers, have already made a fair start toward renewing the forests. Too little care is usually observed in protecting this young growth, which is admitted to be of no value at the present time. Because there are no dollars in them now the proprietor is likely to let them go to waste. In very few instances in moist climates would it be necessary to plant trees started in the nursery.

The writer has often been asked by bright young men of no resources except their active brains and hands, "What is there in this country to encourage a young man, who must earn his living as he goes along, to make a specialty of forestry? I like the subject, and if I saw a good living in the business I should run the risk and go ahead." I am free to say that so far work in this field seems to be done gratuitously.

A few persons in our agricultural colleges have done a little in this direction, mainly to call the attention of students to the magnitude and importance of a study of forestry. Before any one of us thought much about trees the courses of study in these colleges were replete to suffocation with subjects of seeming importance. Elective courses are expensive. The writer has twice given a course of lectures daily for twelve weeks to members of the senior class of the University of Michigan, or to those who elected forestry. A course of parasitic fungi runs parallel with that on forestry, and only one of the two can be elected. No doubt there have been similar reasons in the other schools to prevent giving more attention to forestry. But if we are interested and make the effort we can all find some opportunities for this work.

Lectures at farmers' institutes now held in many states afford some opportunity. But here the indifference of the hearers tempts us to select other subjects. Vividly does the writer call to mind one occasion at an institute in a new county in which he spoke of the importance of preventing forest fires. The first one to lead in the discussion was a farmer living in the neighbourhood, who won the applause of the audience when he said of these fires, "They are the best friends we have in clearing up the country."

The more students know about trees, the more they are likely to be interested in this subject. The things to be learned are the different species, their names, their anatomy and physiology, their rate of growth and geographical distribution, their special uses in the arts and in nature, how to raise trees from the seeds, how to plant and where to plant and why, and especially how to take proper care of them after setting. He who fully understands the structure and functions of roots will never be seen carting living trees with roots exposed to dry wind and sun for miles along the highway. Students may be set to investigating the effects of pasturing a wood-lot by noting examples of those pastured and those left to themselves. They may estimate the amount and value of an acre of good, medium or thin forest, and note the time required to produce it. The effect may be noted of trees as a shelter along the highway or near dwellings, barns and sheds. Other questions are, why are certain trees found growing in swamps and others on dry land? Why are there no pines or cedars in some neighbourhoods, and no beeches or maples in others?

Besides the means suggested for aiding the cause there are others. If the programmes were judiciously prepared and well carried out the celebration of Arbour Day by school children would have a tendency to awaken an enthusiasm among the people, but usually the exercises consist mainly of quotations from literary authors—scraps of poetry, history and sentiment—rather than any substantial information pertaining to the needs of forestry. The establishment of an arboretum, even a small one on some of the farms of enterprising people, and more especially at each agricultural college and experiment station, would help to educate and interest the people. We cannot soon expect to see an Arnold arboretum in every state, but the beneficial influence of that garden has already reached thousands of miles.

Associations for securing the protection of certain private natural scenery help to educate everyone who sees the reserves. Botanic gardens containing shrubs and trees are likely to increase in numbers, each good one lending encouragement to others. So of herbaria, and especially of museums of plant products, which should contain no end to interesting specimens of timber—not only those which were well grown, but likewise all manner of monstrosities. The writer a few years ago collected and placed in position a unique collection of this kind, and, considering the cost, it was more attractive than an

ordinary museum of fossils, minerals, or stuffed animals. Who can tell the good results likely to occur to forestry from the establishment and maintenance of the Jesup collection in Central Park, New York?

Several books have appeared that are worthy of notice, but none of them can be compared with "The Silva of North America," by Professor C. S. Sargent, the first four volumes of which have been published. In several states reports have been issued by forestry commissions or forestry associations, or special bulletins on the subject have been published by experiment-stations. The United States Government has, through Mr. Fernow, the efficient head of the Forestry Division of the Department of Agriculture, for some years past been active in advocating measures of importance in relation to forestry. Bulletins and reports and gratuitous lectures and frequent conferences with congressmen have all had their effect in awakening an interest in this subject. There are several journals, notably *Garden and Forest*, which have exerted a good influence in behalf of tree-protection, and such articles as the *Engineering Magazine* has published lately on the great waste of lumber still in progress are of value in properly educating the public mind.

From the condition of things here outlined it will be seen that the growth of an interest in forestry must be slow for some time yet, but I anticipate very great changes in the sentiment of our people and the formation of salutary laws by the close of this century.

ST. THEODORE, VENICE.

THE Venice correspondent of the *Scotsman* writes:—In 1127 three giant granite monoliths, each about 50 feet in height, were brought to Venice from the East. They were bought and paid for, and not stolen, as everybody says. One lies buried in the lagoon in front of the Doge's Palace, and the other two were set up in 1173, and these are they that now so majestically grace the entrance to the city from the Piazzetta of San Marco. In or about 1200 the two patron saints of Venice were set upon their summits—St. Theodore standing on a crocodile on the one, and St. Mark under the symbol of a noble lion on the other.

For nearly seven centuries they have stood on their noble pedestals keeping watch and ward over the Queen of the Adriatic at their feet. But in these recent days both saints and pedestals showed signs of decay, and it was feared if nothing were done Venice might wake up one day to find that her long-neglected saints had become her destroyers. Accordingly, the Great Lion of St. Mark and its pedestal were first examined and repaired. Then St. Theodore and his crocodile and his pedestal were subjected to the same scrutiny and kind treatment, and I purpose telling in few words the story of that, with the strange discoveries it has led to. First, St. Theodore and his crocodile were brought down to the ground. He was found to stand 10 feet in height, and his animal measured 14 feet in length. Both were made of Greek marble, bound together with iron coated with bronze. As only in Athens iron was so coated, a Greek origin was suggested. On closer examination it was found that half the marble was good and half was bad. Then it was discovered that half the workmanship was good and half bad. The head and upper part were of good material and well carved; the lower half of the body, like that of Nebuchadnezzar's image, is base in material, and besides it is base in execution. Then it was discovered it was not St. Theodore at all, nor one homogeneous person even. The figure has the head and bust of a Roman emperor, with the lower part of the body and limbs of some inferior person. But the legs of the figure and the part of the body of the crocodile on which it stands are one piece of marble, and a closer examination of the animal showed that its form was as much that of a dragon as a crocodile.

A good deal of discussion has been carried on concerning these matters. The opinion that is gaining ground is that of Sig. Vendrasco, who is the clever engineer in charge of these monuments, that the upper part of the figure is that of the Emperor Constantine, with his crown of laurel and breastplate with the Christian cross on it and decorated with eagles and lions, and that the lower part is that of an inferior Greek statue. A curious fact is that the shield is on the right arm, whilst the left hand holds the spear. The spear is wood coated with bronze. What is certain is that it was set up to represent St. Theodore and his crocodile, which is the main thing. Now for what has been done. The statue was originally in seven parts; it was broken into 100. The abacus of the column was shattered. The capital was not a solid block of marble, but a hollow cylinder filled with bricks and rubbish, and the rain entering and the frost affecting it, it was split vertically and horizontally. The huge monolith, weighing with capital, base and statue over 100 tons, leaned, like Pisa's Tower, a long way off the perpendicular. Signor Vendrasco has straightened the column, which, unlike its sister companion, goes into a socket over a foot in depth. He has

bound up with copper girders the capital, repaired and relaid the abacus, and he has made a new man of St. Theodore and set him up once more on his crocodile's back on his lofty pedestal. He has made a lighter man of him, for he has taken out of him over 2,000 lbs. of lead and 300 of iron and 150 of copper. The work was only completed the other day, but it is hoped no time will be lost in removing the unsightly scaffolding so that Venetians may once more be able to see their saints, and visitors, who are now pouring into Venice, may be able to see in all their symmetry and beauty these ancient historic monuments. As in the case of the Great Lion here, casts of St. Theodore and his crocodile have been taken, which will be sent to Rome, Paris, London and New York in all probability.

EDINBURGH ARCHITECTURAL ASSOCIATION.

ON Saturday afternoon a large party of the Edinburgh Architectural Association, under the leadership of Mr. Hippolyte Blanc, A.R.S.A., visited Prestonkirk, Whitekirk and Tynninghame, with the remains of the priory there. At Prestonkirk the party were met by the Rev. Mr. Marjoribanks, who kindly placed the church open. Mr. Blanc explained that the existing building was believed to be on the site, and indeed partly on the foundations of the original church, and was perhaps the oldest ecclesiastical foundation in the Lothians, a religious house having been established there by St. Baldred towards the end of the sixth century. The most interesting part of the visible remains was the chancel, of the thirteenth century, the exterior of which remained nearly entire, a beautifully proportioned piece of work. Proceeding to Whitekirk, the party were received by the Rev. Hately Waddell. Mr. Blanc, by the aid of a number of specially prepared drawings, explained the features of the church in plan and detail, all the parts of which indicated the fifteenth century as the period of erection. The original church on the same site he noted as having been erected in the twelfth century as an offshoot from Tynninghame. The structure was afterwards examined by the party, who, by the kindness of Mr. Waddell, were shown several interesting belongings of the church. Driving by the Binning Wood to Tynninghame House, the party were received by Lord Haddington, who personally conducted them, and exhibited the rich treasures in paintings, relics and curios, of which the house is abundantly possessed. The interesting remains of Tynninghame Priory, so well preserved in the grounds, were also visited, and were explained by Mr. Blanc to represent the chancel and apse arches of a once very important edifice, erected along with Lindisfarne Priory, to which it was attached in 1093. By a plan of the remains, and also a plan of Lindisfarne Priory, it was shown that the dimensions, so far as they could be compared, were nearly the same in both. The rich detail of the ruin was examined with considerable interest. The several gentlemen who had contributed to make the places visited instructive were duly thanked, and before leaving Mr. W. W. Robertson expressed for the members their appreciation of the courtesy and kindness shown them by Lord Haddington.

TESSERÆ.

The Palace of Spálato.

AS the first consistent arched interior, the hall of Diocletian's palace contains in it the germs of all later architecture; the germs not only of Ravenna and Pisa, but of Caen and Durham; not only of Caen and Durham but of Westminster and Amiens. As such there is no more memorable building upon earth. But it is in no way wonderful that the great improvement which it offered was not at once universally accepted. Every architectural development has to go through a stage of transition, a stage when the new principle and the old are striving for the mastery, and when the two are mingled together in various degrees and proportions. The architect of Spálato showed that columns could be used as the immediate supports of arches; he did not at once persuade the whole world to use columns as the immediate supports of arches. Men had been so long used to look upon the entablature as the right thing to rest upon the capitals of the columns that they could not all at once bring themselves to let the arch come straight down upon the capital itself. It seemed as if something must be done, as if some change must be made, to adapt the capital to its new duties. Something must be thrust in between the capital and the arch; some fragment, as it were, of the entablature, must come between the abacus of the capital and the impost of the arch. Or perhaps the abacus itself must be enlarged into something like a piece of entablature, or the whole capital must be drawn out to an unusual size and height, in order to seem more worthy of its new prominence, and better able to bear the weight that was laid upon it. For it is manifest and it is one of the great advantages of the arched construction, that the

columns or other supports of a range of arches, may be placed at much greater distances from each other than the columns of a colonnade supporting an entablature. It follows that each column and its capital assumes in the arched building a greater importance; it has, so to speak, a more distinct separate existence than belongs to the columns of a colonnade. In the later Roman architecture we therefore find all kinds of shifts to avoid that immediate juxtaposition of the arch with capitals of the hitherto accustomed forms on which the architect of Spálato had already ventured.

Architecture and Social Life.

The history of architecture, like that of the other arts, marks out the progression of manners. Among the Dorians it carried with it the austerity of their national character, which displayed itself in their language and music. The Ionians added to its original simplicity an elegance which has excited the universal admiration of posterity. The Corinthians, a rich and luxurious people, not contented with former improvements, extended the art to the very verge of vicious refinement. And thus (so connected in their origin are the arts, so similar in their progress and revolutions) the same genius produced those three characters of style in architecture which Dionysius of Halicarnassus, one of the most judicious critics of Greece, remarked in its language. The Dorians exhibited an order of building like the style of their Pindar—like Eschylus, like Thucydides. The Corinthians gave their architecture that appearance of delicacy and effeminate refinement which characterises the language of Isocrates. But the Ionians struck out that happy line of beauty which, partaking of the simplicity of the one without its harshness, and of the elegance of the other without its luxuriance, exhibited that perfection of style which is adjudged to Homer and his best imitators.

Paints in Venice.

It is well known that the Venetians were abundantly supplied with the finest colours of every description; their great trade with the East rendered the acquisition of them easy. When Philip II. ordered Michel Cocxie to copy the famous altar-piece of the *Adoration of the Lamb*, by the Van Eycks, Cocxie complained that he should not be able to procure a blue of sufficient excellence for the drapery of the Virgin, whereupon Philip wrote to Titian for some ultramarine, which he procured, and it was of so costly a kind that Cocxie used for the drapery of the Virgin about a quantity of the value of thirty-two ducats.

Lawrence as a Portraitist.

If ever there was an artist who reduced everything that he attempted to the level of his own capacities, it was Sir Thomas Lawrence. Unquestionably a man of genius, he was more than a mere copyist; he painted men and women, and not mere faces. But as his own intellect, feelings and tastes rose only to a certain limit, and were imbued with a certain peculiar and unimaginative spirit, so he comprehended only a certain fragmentary portion of the minds of his sitters, and transfused into them all alike a measure of that semi-refined, semi-intellectual, semi-graceful and artificially-polished sentiment which was so strikingly exemplified in his own feelings and intelligence. Sir Thomas Lawrence embodied the spirit of the cultivated English drawing-room and conversazione. In scarcely any of his pictures did he conceive of any character in which the artificialities of civilised life did not exercise a most powerful sway. His gentlemen and ladies are always dressed for the evening, never vulgar, never *outré*, never stupid, never commonplace, never exaggerated, but never great. The gentleman and the lady is more prominent than the man or the woman. He did not paint for mankind; he did not even paint for his own generation; he painted for the class of society who took him up and patronised him and bought his pictures and thought him the first of geniuses and the most gentlemanly of artists. The hand—that portion of the human frame in which high birth is supposed pre-eminently to display itself—was elaborated by him with as much care as the most speaking feature in the countenance, and in truth, in our judgment, it was sometimes the best part of his pictures. In a word, he painted up to his own conceptions of that which is valuable, estimable and enviable, and there he rested. Turn, then, from the inanities of these days to the portraits of a Raphael, a Rubens, a Vandyke, a Velasquez, a Titian, or even to those of a second-rate class, as of our own Reynolds or Gainsborough. Who does not feel in a moment that, in contemplating their noble works, he is communing not only with the men of other days whose countenances he beholds, but with the thoughts and conceptions of the painters themselves? Those glorious portraits are poems every one of them. They are like the episodes in an epic, which give us little touches of human feeling and human character, and at times can move our hearts and call forth our veneration more powerfully than the most triumphant achievements of professed historical art. Like the characters of Shakespeare, they are for all ages and all nations. What is it to us that they

are clad in the garb of Romans or Venetians or Spaniards or Englishmen? It is their true, living, breathing humanity that gives them their imperishable charm. They are not merely the outsidings of men; they are the forms in which the minds of other days were clothed; and when we stand and watch their speaking lineaments it is not alone the wondrous skill of the painter that rivets our attention and stimulates our feelings; it is the consciousness that we are carried back centuries in the history of our race, and almost privileged to converse with the very men who figured among the most celebrated of the earth, and were cast in the same mould in which we ourselves are still formed. And when we recur to the recollection of the artists who spread the glowing tints upon the canvas it is not so much an admiration for their skill in all the learning of their craft of which we are conscious as a respect for their lofty intellects, their cultivated taste, their poetic genius, and their knowledge of human nature.

Cluniac Churches in England.

Pomp and splendour were the characteristics of the superb churches of the Cluniacs. They were radiant with colour, blazing with crystal, jewels and crowns of light. The parent minster at Cluny, with its vast apse girdled with marble pillars of huge size, its double transept and splendid lanterns, produced no building so solemn and imposing in this country. Here they betray caprice, irregularity and utter contempt of orderly arrangement. The cloisters of Wenlock and Lewes seem to have had their surrounding buildings thrown at haphazard upon the ground. We find instances both of oblong and apsidal chapter-houses. Perhaps a shallow transept, imported from continental examples, is one of the principal characteristics of the Cluniac churches. The ante-church may be traced at Lewes, which has also the rare feature of a coronal of chapels clustered round the aisles of its central apse. In Castle Acre and Wenlock we trace the fulfilment of careful and good design. The Cluniac order had only thirty-two English houses.

The English Standard.

The pictured representation of the great fight of Senlac (which we call the battle of Hastings), which has been transmitted to us by the needle of Matilda, the Conqueror's queen, does not give us anything like distinctive colours in the Norman army. Before the Saxon Harold is borne the national standard of the dragon, but William and his followers simply attach to their lances small swallow-tailed flags of white, with coloured crosses and borders, bearing a great similarity one to another. In the battle of the Standard, about a century later, though the English had a general ensign of such size and importance as to be drawn upon a four-wheeled carriage to the battle-field, it consisted of two ecclesiastical banners, those of St. John of Beverley and St. Wilfrid of Ripon; the figures, that is to say, of those holy men, embroidered upon the hangings in use at that date in churches and processions, which were brought into action more from a belief in their miraculous powers than as a national distinctive emblem. It is somewhat remarkable that the famous French standard, the oriflamme, or flame banner, anciently belonged to the abbey of St. Denis, near Paris, and was borne by the kings of France, in honour of St. Denis, in right of their possession of the territory of the Vexin, whose counts were patrons of that church. The devotional turn given by the Crusades to the warlike spirit of the age brought the cross into use as a national English distinction, though its colours at first were the exact reverse of those afterwards appropriated to the banner of St. George (red upon white), which still "flings its crimson blaze" wherever the meteor flag of Britain, the Union Jack, floats over ocean. But the effect of the Crusades was to introduce a fresh fashion, from whence the modern science of armorial bearings took its rise. The scorching heat of the climate of Palestine made it absolutely necessary to protect the warrior from the rays of a blazing sun by some covering less susceptible of receiving and retaining heat than armour of metal, and from plain loose frocks of one colour, the surcoats, as they were called, gradually became embroidered records of the prowess or rank of the wearer. Hence the term coat-of-arms, and the introduction of rules to define in what way they should be ornamented, and to prevent the confusion which would soon have arisen if any other person than the immediate relations of the warrior or noble originally adopting a device had been allowed to copy and appropriate it. When we remember where and under what circumstances heraldry took its rise, we shall not be surprised that the lion became the favourite symbol of the warlike nobility who were battling against the Saracen power in Palestine. The magnificent quadruped, whom we call the king of beasts, would be an object of tenfold admiration to those who saw him for the first time, or heard his strength and noble bearing described in the poetical phraseology of the East. The lion was adopted by several crowned heads as their personal cognisance; and, the fashion spreading, our Anglo-Norman nobles soon learned to regard him as the only animal worth bearing on their shields. Richard himself could do no less,

in justice to his name of "Lion-heart," than adorn his shield with the representation of a pair of lions leaping up to fight each other, the first regular arms assumed by an English monarch, shortly exchanged by him for the familiar three lions of our present royal arms. Some time, however, elapsed before the personal ornaments of the sovereign were converted into a national flag; and it is not until the reign of Edward I. that we find the king's banner, joined with those of St. George and St. Edward, triumphantly floating from the battlements of the Scottish fortress of Carlaverock, which had surrendered to his troops. In fact, at that time the royal banner would not have been displayed except where the king fought in person, and sometimes not even then, if, by way of compliment to some eminent leader, he desired, as our fighting Plantagenets occasionally did, to serve as a volunteer under him. Still slowly, as heraldry became more familiar to the people, more bound up with the associations of everyday life, and as the constitutional progress of national government gave more influence to the monarchy, the lion became more and more naturalised as the symbol of representation of the national sovereignty.

The Outer Parts of Roman Houses.

The Romans, while fond of public life, were jealous of the privacy of their domestic arrangements. As regarded the public portion of their houses, access was readily attainable, but they were not accustomed to entertain guests, and when they did so lodged them usually in separate buildings rather than under their own roofs, although they occasionally accommodated them in rooms round the atrium or outer hall. The division of a more or less public character contained the entrance, the hall and some of the surrounding chambers and corridors. In the case of palaces or houses of importance there was usually an open space in front. This was called the area. It was sometimes planted, but more often laid out architecturally and ornamented by statues or fountains. The traces of this arrangement survive in the numerous piazzas or open squares of modern Rome. Opening from the area was the principle entrance, approached by a portico or colonnade, which was sometimes arched. This adjunct, so useful in southern climes, served also to give dignity to the mansion to which it was the entrance. It was only applicable as it would be among ourselves to the more important buildings. At Pompeii it is not found, as the space in that small town is too much occupied to allow of it. In such cases the houses had no piazza or area, but there was sometimes a small porch or portico opening on the public street—as in the building which goes by the name of the House of Diomedes. The latter feature was at first reserved as a privilege of the great, but after the time of Nero it became common and was in ordinary use in the improved houses built at Rome after the great fires of that emperor's reign. The porticos served to break the monotony of the streets and afforded an agreeable shade, not only to the entrance of the houses, but also to the shops which usually flanked them. At Pompeii the streets are too narrow for porticos, and their monotony and poverty of architectural effect are mainly due to this circumstance. Between the portico and the atrium we find the vestibule, serving as an outdoor waiting-room or approach to the house. The arrangement is not without architectural importance. However striking a building may be, the eye requires to be gradually introduced to it, and the effect of an interior is greatly enhanced by a proper mode of approach. In the palaces of the Romans vestibules were usually found, and Vitruvius says that in the mansions of great people they should be spacious and dignified. In smaller houses the vestibule was, of course, on a reduced scale and was sometimes altogether omitted. In Pompeii it is found occasionally, but not in any case of large size. The arrangement of a vestibule is still found existing in the great churches of Rome, such as St. John's Lateran and St. Peter's. It is, of course, only suitable on an extensive scale to important edifices of considerable dimensions and of some architectural magnificence. Entering the portico and then the inner doorway through the vestibule, the great hall or atrium is seen beyond, but between the door and the atrium is a corridor or outer hall. This latter was called the prothyra. It was not only the entrance to the house, but also served as a means of access to the apartments on either side, which in small houses were sometimes shops where the proprietor sold the produce of his farm or other property. In large houses they served as inner vestibules or rooms for porters or slaves. The possession of a doorway in the street being reserved as a special mark of honour, the meaner dwellings had to be content with doors from the prothyra. There were in some cases more than one door, so that the master of the house should not be obliged to pass through the crowd of servants or dependents who thronged the vestibules and outer corridors of the mansion. In the prothyra was the place for the porter or the guardian of the door and sometimes a dog was kept there. It was this custom which led to the representation of dogs in mosaic or in painting on the floor or walls, as we find in some cases at Pompeii.

NOTES AND COMMENTS.

THE Madeleine in Paris is a building in which the least attempt at decoration is difficult. From its Classic character and the unity which is throughout, the church appears complete, and additions run the risk of being regarded as excrescences. The *Curé* has been, however, of opinion that the semi-dome of the sanctuary, on which M. ZIEGLER has depicted a multitude of figures to form a sort of history of Christianity, is in too harsh a contrast with the white marble of the screen behind the altar. He was able to persuade the Government that it would be advantageous to interpose a band of mosaic, and about five years ago a commission was given to M. LAMEIRE, who is one of the great masters of decoration in France. Several of his works have been illustrated in *The Architect*. The execution was confined to M. GUILBERT MARTIN, who has sacrificed much to establish mosaic as a French industry. The subject selected is the triumph of the Church in France. CHRIST is the central figure, and He is accompanied by the saints whose names are associated with many French churches—MAXIMIN, ISIDORE, MARTIAL, FRONT, FLOUR, TROPHIME, EUTROPIUS, URSIN, JULIEN, DENIS. There are also figures of Saints MAGDALEN, VERONICA, MARTHA, MARIE-SALOME, MARCELLA, &c. It is not necessary for an assemblage of such figures, which are nearly double life-size, to display strong colours; the nearer to white they are the more successful they become. But as there is so much ormolu about the building it was necessary to have a gold ground. This caused much difficulty. It was feared that so large a mass would be too glaring and hard. After many experiments M. MARTIN succeeded in introducing a variety of tones among his gold tesserae, and if there is now less of mechanical uniformity there is compensation in the softness which is produced. The decoration is a very successful work, and it atones for such fiascos as the mosaic work in the Louvre.

SINCE France has possessions in Africa it is only rational that the "Art Mussulman" should be nurtured. That is a better course than ours, for we must have astonished the Easterns when we sent raw youths who had gained one or two certificates to expound to them the mysteries of form and colour in ornament. Afterwards there was a reaction, of which one of the consequences is likely to be the exhibition of Eastern rubbish in the Imperial Institute. The French are acting more carefully. They do not either overvalue or undervalue the art of Algiers or Tunis. They allow it room to grow, and they try to understand it. In July an exhibition of the art of the Mussulmans will be held in Paris. It was contemplated that the late JULIUS FERRY should preside over the arrangements, but that office has now fallen to M. SCHEFER, the administrator of the School of Eastern Languages. The manager will be M. MARVE, the conservator of the Musée at Algiers. There is little doubt that the exhibition will be a success, although it is only Africans who can appreciate visits to the galleries of Paris in July.

THERE can be no doubt that the late WILHELM LÜBKE was a worthy representative of German scholarship and industry. He could turn out books that related to art with the regularity of a machine, and apparently without any mental or bodily inconvenience from his unceasing production. Publishers believed in his system, and they spared no expense to supplement his descriptions with woodcuts. The pile of big volumes which bear LÜBKE's name on the title-page will appear less remarkable if we remember that he was a professor in a great many colleges, and that it was safe for him to print his lectures, for before the opportunity came for redelivering them he was likely to be in another classroom. WILHELM LÜBKE was born at Dortmund in 1826. His ambition was to teach, and he studied philosophy in Bonn and Berlin. But in a region where everybody can expound philosophy there are many competitors for every office connected with it, and LÜBKE prudently turned his attention to the history of art. He was fortunate in gaining the position of teacher of the history of architecture in the Berlin

Academy of Building in 1857, and henceforth his course was marked out. Four years afterwards he was invited to become Professor in the Zurich Polytechnikum, which he accepted. In 1866 he received a call from Stuttgart, where he remained for several years, and then he went to Carlsruhe, where he remained until his death. His unceasing industry at his desk affected his eyes during his latter years. LÜBKE deserved all the respect which he enjoyed. He made the knowledge of the history of art acceptable to all his countrymen, but it may well be doubted whether German artists would not be more successful if they were less hampered by the belief that every detail of their work must be in accordance with something or other that is recorded somewhere in a book.

FOUR architects who have already carried out churches in Ireland were invited to send in designs for the Roman Catholic Church which the Rev. CANON WHITE is about to erect in Nenagh, co. Tipperary, and which is to cost 20,000*l*. The qualities of two of the designs were so equivalent, it was decided to submit the drawings to Mr. DREW, R.H.A. He also was puzzled to decide which deserved preference. No. 1 he estimated to cost 22,500*l*, No. 2, 23,120*l*. No. 1 appeared to Mr. DREW as "the perfection of that fine type of Catholic church which has been developed in Ireland in the latter part of this century," but his own preference was for No. 2, on account of "its recurrence to more ancient and traditional treatment of style than obtains usually in modern church building." Eventually the design by Mr. WALTER DOOLIN, M.A., of Dublin, was selected, and the second prize of fifty guineas was awarded to Mr. G. C. ASHLIN.

THERE are many topics in Colonel HAYWOOD's report on the works executed by the Commissioners of Sewers which are worth notice. The drainage could not be extensive, but it is noted with satisfaction that two ventilating flues were carried up in connection with the City Bank, Ludgate Hill. Although the Commission since 1884 have been trying to construct them, it is owned that "very little hitherto has been done in such constructions, there being the greatest difficulty in inducing owners of property to consent, and in some cases exorbitant rents have been demanded." Street improvements are not easily carried out owing to the value of land in the City. But the removal of Sam's Coffee-house, in King Street, Aldgate, enabled the street to be widened by at least 6 feet. In rebuilding premises in the Minories, near Aldgate, an encroachment was made beyond the line of improvement sanctioned by the Commission. The new buildings were of a very substantial character, and the encroachment was not discovered until they were completed and the hoarding removed. The buildings were ultimately permitted to remain on the delinquent paying a fine of 500*l*. It is reported that the widening of Ludgate Hill is now completed, after a lapse of twenty-eight years. It is said that projecting sign-boards have of late years become very numerous in the City. A report upon them was prepared by Colonel HAYWOOD, and amended regulations were subsequently issued in respect of them. The contest between gas and electric power for street illumination continues. The gas lighting in the main thoroughfares was discontinued from time to time as the electric lamps were put into operation. The gas lamps and fittings, however, were not removed, arrangements having been made with the gas company for cleaning and maintaining the lamps ready for lighting to meet the contingency of failure in the electric light. The number of gas lamps unlit at the end of the year was 1,126, the number of arc lamps lighted being 409; 275 gas lamps were extinguished for each arc lamp. Colonel HAYWOOD having required the electric light company to place experimentally glow lamps within the gas lamps in such manner as to leave the gas available in the contingency of failure, the gas company raised various objections to that being done and stated their intention of removing the gas fittings when the glow lamps were placed inside the lanterns. The question was still under consideration of the Streets Committee when the report was issued.

THE ANGEVINE CHURCHES.

THE architecture south of the Loire is different from that of the northern part of France. The northern architects aimed at height, the southern at breadth, their object seeming to have been to cover the greatest possible space with a stone vault without pillars or arches.

According to some well-informed French antiquaries, says the late J. H. Parker, the original type of these peculiar churches was the cathedral of St. Frond at Périgueux, and this is said to have been built by a Venetian colony very soon after St. Mark's at Venice, or between 976 and 1047. The very massive character and extreme plainness of that building agrees very well with the early date assigned to it, and the use of the Pointed arches to carry the cupola may be accounted for by its Eastern origin. However this may be decided, the general character of these buildings is clearly Byzantine; each bay is square and covered by a domical vault or cupola, in some cases lofty, in others nearly flat, and concealed externally by the roof.

Mr. Parker's impression was that these churches were generally of the twelfth century, and he found in the same district another description, also of very fine character, which appeared to be of the eleventh. The latter are of the usual plan, with narrow aisles, barrel vaults and massive round arches, the capitals and bases and the general character of the work agreeing with that of the eleventh century, as for instance with the churches at Caen of the time of William the Conqueror. But some in Poitou are much larger and finer than are to be found elsewhere of that period. May we venture to conclude that this part of France was in a very flourishing state in the eleventh century, and its architecture consequently in advance of other parts?

This state of prosperity appears to have continued through the twelfth century and then to have suddenly ceased. Scarcely any churches appear to have been built between the twelfth and the end of the fifteenth century. This interval exactly agrees with the period of the English dominion, which seems to have been a continual struggle, and the constant state of civil war was not favourable to the building of churches.

The cathedral of St. Maurice, at Angers, is a very striking and important building; the earliest part is the nave, which is of about the middle of the twelfth century. It is 54 feet wide and 80 high, divided into bays or compartments, which are nearly square, and each is covered by a domical vault, not a plain dome, but the central point is the highest, and the ribs, which are square and enriched with the zigzag, meet in this central point; they are on the groins, the space being divided into eight cells. The bays or compartments of the church are separated by massive square-edged arches, which are slightly pointed, and are carried on enormous buttresses, about 10 feet square at the sides and 14 feet at the angles; whilst the cornice or corbel-tables and strings are carried round them, so that they form rather a thicker part of the wall than buttresses in the ordinary sense. Between each pair, or in the side-wall of each compartment, is a low pointed arch, recessed in the wall, springing from the bases of the piers, and carrying the triforium gallery at about half the height of the walls. The windows are entirely above this gallery; they are round-headed, in couplets, and filled with very fine original glass of the twelfth century, very similar to that at Canterbury. The inner face of the square buttresses is ornamented with shafts, having capitals and bases of Norman character: these carry the transverse arches and the ribs, and complete the design; the triforium gallery is supported by a Norman corbel-table. The west front of this church is very fine and rich, though somewhat spoiled by alterations at the period of the Renaissance. The central doorway is perfect, its jambs and tympanum filled with fine sculpture, the figures of the stiff Byzantine character. The rose-window has been destroyed and the arcades mutilated, and in the upper part a range of figures under canopies, and a sort of cupola of the Renaissance style, have been introduced in the place of the original gable. The two side towers remain, and have rather good flamboyant spires added to them. The next part of the church is the choir with its apse, which are of more decided Transition character, and belong to quite the end of the twelfth century; while the transepts, though still partaking of the Transition character, are said to have been built as late as 1240. There is a fine rose-window at the end of each transept; the southern

one is the earliest, and of plate tracery. Flamboyant chapels have been added on both sides of the nave near the west end, and there is a cloister of late date on the south side joined on to one of these chapels. Both the cloisters and chapels appear to have been rebuilt on older foundations. The vaults of the choir and transepts have round ribs instead of square. There is some fine original ironwork on the west door.

The church of Ronceray, in Angers, is said to have been founded by Foulques, Earl of Anjou, in 1025, and dedicated to St. Mary the Virgin in 1028, and re-dedicated in 1119 by Pope Calixtus II. It is evidently one of the oldest churches in Angers, and a very fine example of the early type; it is not of Byzantine character, but its plan at present is a simple parallelogram with a plain barrel-vault. To compare great things with small, it bears considerable resemblance to the chapel in the White Tower in London; the details also agree in character with the churches of William I. at Caen. All the capitals have the small volutes, in imitation of Corinthian; and the central piece for the caulicoli is in many left uncarved, a very common feature of the eleventh century. Some, however, are more elaborately carved, as in those of the Holy Trinity at Caen; but, in both instances, the sculpture is probably somewhat later than the rest of the work.

The vault in the church of Ronceray is carried upon plain square-edged transverse arches of semicircular form, and has no other ribs. The windows are plain, round-headed (mostly blocked up); the vaulting shafts are half rounds, and have the capitals before mentioned; the windows are all in the upper part of the wall above a string, below which the wall is plain; the shafts are all cut off at about one-half their length, and have modern corbels. It had originally apses, aisles and transepts, which were destroyed in the last century.

The ruins of the church of St. Laurent, Angers, near to that of Ronceray, are of similar character, though not, perhaps, quite so early. The plan is cruciform, with an apse to the choir, and an apsidal chapel on the east side of each transept. The vaults are destroyed, but the greater part of the walls remains. It is chiefly of slate, the principal building material of the district, but there are tiles mixed with it. The windows have shafts, the capitals of which are of rather a Greek character; the work shallow, but with volutes in the angles. The masonry and the character of the work is very rude. The vaults of the transept apses remain, and are of the half-dome form, constructed of small square stones in regular courses. The vaulting shafts and springing of the transverse arches show that the other vaults were barrel-shaped, like that of Ronceray.

Another ruined church of great interest from the character of antiquity and the peculiar features it possesses is St. Martin, Angers. The plan is cruciform with a central tower and without aisles; the walls of the original portions are built of squared stones in layers, alternately with layers of tiles, three rows together, having an equal thickness of mortar between each row, exactly as in Roman work. The nave is in ruins and has lost its vault; the central tower is tolerably perfect, and is vaulted with a dome. The piers of this tower are constructed in the manner just described, but they have imposts exactly like the usual Norman impost. There are large shafts in the angles with capitals of the character of the eleventh century, and on these rest small shafts carrying the angles of the vault—an arrangement common in Norman work. The arches are plain semicircular with flat soffits, the dome has a plain surface without ribs. The transepts are of the same style as the central tower. The choir is considerably later and is of Transition character. The vaults domical with square ribs. The apse is still later and almost of early French style, but the vault here has round ribs. All these ribs are enriched with ornament. Monsieur De Caumont states that the nave and transept of this church are parts of the structure erected by the Empress Hermengarde in the beginning of the ninth century, and considers it as a precious fragment of the works of the Carolingian period (now extremely rare).

Trinity Church, Angers, is a very remarkable church, chiefly of Transition character. The nave is wide and has a series of semicircular recesses for altars down the sides vaulted with half domes; the arches pointed and very much enriched with a great variety of late Norman ornaments. The nave itself is vaulted by a series of cupolas or low domical vaults, each divided into eight cells, as at the cathedral. The eastern part or choir is divided into three portions, the choir itself, with two aisles, each having an apse. This triple apse has a fine effect on the exterior. Over the central division is a small tower or square lantern with a cupola. The windows are all plain and round-headed; the arches all pointed and enriched with ornament. The windows of the nave are pointed and more of early French character. At the north-west angle of the nave is an older tower partly in ruins, and clearly of the character of the eleventh century, with a barrel-vault and capitals to the shafts, similar to those of the church of Ronceray, which almost joins on to it; a small part of the wall of the nave is of the same age and work as the tower. The old church to which

this belonged was evidently much smaller and lower than the present one. Part of the surface of the wall of the old work is formed of small diamond-shaped masonry. This church is said to have been commenced in 1062 and completed in 1092; these dates agree very well with the character of the tower and the small portion of the original tower that remains. The present church is about a century later.

In the cloisters of a modern building at Angers, that is now the prefecture but was formerly an abbey, are some remains of the original cloister, which were long entirely concealed under a thick coat of plaster. The work is in very fine preservation. It consists of an arcade of Norman work. It is almost unrivalled, even at that period of rich and elaborate work, the middle of the twelfth century, to which it belongs. In several parts the original painting remains more or less perfect. The tympanum of one arch especially is quite perfect, and very curious from the combination of sculpture and painting. In the crown of the arch is a figure of Christ sculptured and coloured, and the figures form part of the same composition with the painted figures on the flat surface of the wall. These are small groups of Scripture subjects: the Epiphany, the Offerings of the Magi, the Flight into Egypt and the Judgment of Solomon. The drawing of these figures bears a remarkable resemblance to the Bayeux tapestry.

The wall of the original cloister is 5 feet 6 inches thick, pierced by a series of small round-headed arches enriched as described.

The Hospital of St. John, Angers, was commenced by Henry II., King of England and Count of Anjou, the year after his accession to the English throne, or in 1156, and the buildings are said to have been completed in his time. The hall is a fine building, divided into three aisles by very light pillars, carrying Transition pointed arches and vaults slightly domical. It is eight bays in length, each bay having a separate vault; there are, therefore, twenty-four of these small domes, but they are so low as not to interfere with the external roof. They have bold round ribs on the groins of the eight cells into which each dome is divided, as at the cathedral; but these round ribs occur only in the eastern part of the cathedral, which was built after 1200. The chapel is of precisely the same character and equally good, with very light pillars and vaults, as in the hall. The windows are all round headed. The doorways are also round-headed, but richly moulded with very late Norman work. The effect of the chapel has been much injured by altering the position of the altar, blocking up the original entrance, and making a new one in a bad situation. The east end is square, but the vaults are so arranged as to give the effect of an apse. The cloister is good late Norman, or rather Transition; two sides of it are perfect.

The barn is very fine and of the same period; it is divided into three aisles by two ranges of round-headed arches on double shafts. The windows are in couples, with a diamond-shaped opening in the head; the doorway is round-headed, and opens on an external stone staircase. The mouldings are of late Norman character. The cellar under it is large, but very plain, with a good plain vault. The other buildings of the monastery are modern.

St. Serge, Angers, is a church of late Transition character, almost early French, with a strong resemblance to the Hospital of St. John. The plan is cruciform, with short transepts, scarcely projecting, and with aisles to the nave and choir. The most striking feature is that the choir has two rows of tall, slender pillars to carry the vault, independent of the piers and the arches which separate the choir from the aisles. These pillars are said to be 30 feet high by 1 foot in diameter. They have octagonal bases and capitals with foliage of the stiff-leaf character. The vaults are slightly domed and eight-celled, with round ribs meeting in a central boss, which is the highest point of the vault. At the east end is the lady chapel, which is square, with a flat east end; but the vaults arranged to give the effect of an apse, as in the chapel of the hospital. The piers between the choir and aisles are massive and square, with shafts attached, the arches pointed, the mouldings and vaults of the aisles the same as the choir; the windows are round-headed. The transepts are of similar character, but rather earlier, and have round windows of plate tracery at each end. The nave appears to have been originally of the same character, but has been entirely refaced in flamboyant work. At the west end is a large porch, with rather a curious double vault. There is a tower at the south-west angle, unfinished. The exterior is plain and poor.

The castle of Angers is large, of striking appearance and well placed. It is distinguished by an amazing number of massive round towers at short intervals. The material is slate of a dark colour, with layers of white stone at regular intervals, after the fashion of the layers of tiles in Roman buildings. It was commenced in the thirteenth century, under Philip Augustus, but not completed before the fifteenth, under Louis IX.,* but from the extreme plainness of the work

generally it may be of any age. Part of the work must be of the sixteenth century, as the embrasures are evidently made for cannon. There is a small portion of the Roman wall remaining in the open space near the castle. It is faced with small squared stones, with layers of tiles at intervals, as usual.

The tower of St. Aubin is a fine structure of the thirteenth century, and a good specimen of the early French detached towers. The buttresses rise from the ground on all four sides, and it has never had any other building attached to it; the windows are lancets, and the details are all of the same style.

The ruins of an early French church of the thirteenth century, All Saints, Angers, now belong to the museum; the vaults are destroyed, but the walls remain nearly perfect. The plan is cruciform, without aisles; the windows are lancet-shaped, with shafts having capitals with the stiff leaf foliage and round abacus. The east window is a wheel of plate tracery, but of flamboyant work. The vaulting shafts are terminated on the canopies of figures of the same periods. This is also the case with the vaulting shafts of the choir of St. Martin's, which is nearly of the same character. There is a curious double font, oblong, with two basins, carried on an arcade of early French character. It stands in the north transept and is said not to have been moved. Several good tombs and other fragments of Roman and Mediæval work are preserved here, the ruins having been attached to the museum which is at a short distance from them. This museum is a fine flamboyant house with a good staircase, having a curious and very elegant vault at the top. There are a great number of good old wooden houses in Angers of the sixteenth and seventeenth centuries and several of stone also. One called the House of the Merchants, near the river, is attributed to the thirteenth century, but is really plain flamboyant work of the fifteenth or sixteenth.

St. Peter, Saumur, is a fine church of the period of Transition, cruciform, with a central tower, an apse to the choir and apsidal chapels to the transepts eastward. The choir is very narrow and the apse has only a single window, large and round-headed; the vault is a plain semi-dome, but the vault of the choir has flat ribs and the transverse arches are pointed; the vaults are of the eight-celled flat domical form as at the cathedral and the Hospital of St. John at Angers. The transepts are also narrow; the apsidal chapels have semi-dome vaults without ribs. The nave is wider and has no aisles, but side-chapels, which are not original. The vaults are of the same character as those before mentioned. The windows are all round-headed externally, but very large, and some of the inner arches are pointed. The transverse arches are all pointed and square in section. The capitals are very rich with foliage of late Norman character. The church is so constructed that each bay from the west is smaller than the preceding, the eastern bay being very much narrower and smaller than the western; this seems done for the perspective effect only, to make the church appear larger. The exterior of the church is of the usual Angevine character, and shows very clearly the Transitional date. The apses are very distinct and have round buttresses. The tower by itself might be called early French, but it is all of the same period. There is a rich late Norman doorway on the west side of the south transept. The west front is of the seventeenth century. The tooth-ornament is used in the dripstones and in some other situations. There are arcades of panelling along the surface of the walls both internally and externally.

St. Nicolas, Saumur, is a small church of the usual Transitional character. It consists of three parallel aisles of nearly equal width and height, five bays in length, each bay having a vault of the eight-celled domical character; the arches are pointed. The chief peculiarity of this church is that the altar has been removed from the east end to the west and a modern choir built for it, while the original apses at the east end have doorways pierced in them. This change has obviously been made for convenience, because the church is situated at the western extremity of the town.

The Hôtel de Ville is a small but very good flamboyant building with fine machicolations on the exterior; these have trefoils between them, and add much to the picturesque character. The interior court is richer and also good in its way.

At Candès, near Fontevault, is a fine village church on the south bank of the Loire, of the same late Norman and Transitional character which prevails in the neighbourhood. The plan is the usual one but good and well marked; the choir has a considerable decoration towards the north. The west front is a fine example of Transition work approaching more to the early French character. There are two square corner turrets, which have machicolis at the top, evidently intended for defence. The west doorway is small, of early French style, deeply recessed, having five shafts on each side, and the arch well moulded. Over this doorway is an arcade resting on a corbel-table. The buttresses on each side of the doorway are almost turrets, square at the bottom, octagonal above, and terminated by small spires against the wall of the west gable, with a circular window between them. On the north side of the nave is a very remarkable porch with a room over it as

* De Caumont, "Bull. Monumental," ii. 330.

high as the nave itself, and defended by machicoulis. The vault of the porch is supported by a central pillar like a chapter-house; the work is unfinished in several parts. There are niches in the front, some of which have figures in them; others the plain stones, not carved, showing the practice of carving the figures after the stones were placed, which may be observed in many other instances, but seldom so distinctly as here, some having the figures carved and the pedestals left unfinished. The windows on this side the nave are of enormous length and very narrow; the height is fourteen times the width; the heads are round. The nave has two aisles of the same height with the central division, and these long windows give ample light to all these divisions. The pillars are very tall, octagonal in plan, with clustered shafts having small capitals, each with square abacus and foliage. The bases are of early French character with the deep hollow to hold water and corner foot-ornaments.

Bygones.

"Antiquity after a time has the grace of novelty."—HAZLITT.

THE ARTS IN GREECE.

WHEN Emerson said, "In the Greek cities it was reckoned profane that any person should pretend a property in a work of art, which belonged to all who could behold it," he was no doubt thinking of the essay by Arnold Heeren, which was translated into English by Mr. Bancroft, the historian. The theory that the public can have any claim on the property of individuals, whether consisting of works of art, gold, houses or lands, was probably more repugnant to collectors of pictures and statues than to any other class of owners. But in modern England there is fortunately an admission of the advantage of the Greek principle, for costly works are nearly every year presented for the enjoyment of the people. It would be an advantage, however, if the future destination of their property could be foreseen by all such generous people when they started gathering works of art, for more care would be taken in the selection. But let us turn to Heeren:—

The encouragement of the arts is in our times left chiefly to private taste, and is greater or smaller according to the number of amateurs. The state takes an interest in them only to prevent their total decay or for the sake of some particular design. The case was entirely different in the period when they flourished among the Greeks. The arts with them were exclusively public and not at all an affair of individuals. They afterwards became so, yet never in the same degree as with us; nor even as with the Romans. These positions require to be further developed and more accurately proved. By the arts we mean the three great branches of them, architecture, sculpture and painting. On each of these we have some remarks to offer.

Architecture is distinguished from the two others by the circumstance that its object is use no less than beauty. Not only the moderns but the Romans of the later ages endeavoured to unite them both, and in this manner private buildings became objects of art. Among the Greeks a tendency to this seems to have existed in the heroic age. In the dwellings and halls of the kings there prevailed a certain grandeur and splendour which, however, we shall hardly be willing to designate by the name of scientific architecture. When the monarchical forms disappeared and living in cities, and with it republican equality gained ground, those differences in the dwellings disappeared of themselves, and everything which we read respecting private houses in every subsequent age confirms us in the idea that they could make no pretensions to elegance of construction. It would be difficult to produce a single example of such a building. But we find express evidence to the contrary. Athens was by no means a fine city like some of our modern ones, in which there are whole streets of palaces occupied as the dwellings of private persons. A stranger could have been in Athens without imagining himself to be in the city which contained the greatest masterpieces of architecture. The splendour of the city was not perceived till the public squares and the Acropolis were approached. The small dwellings of Themistocles and of Aristides were long pointed out; and the building of large houses was regarded as a proof of pride.* But when luxury increased the houses were built on a larger scale; several chambers for the accommodation of strangers and for other purposes were built round the court, which commonly formed the centre; but all this might take place and yet the building could lay no claims to beauty. If a town, which was, it is true, but a provincial town, may be cited to corroborate this, we have one still before our eyes. A walk through the

excavated streets of Pompeii will be sufficient to establish our remark. Where the pomp and splendour of the public edifices were so great as among the Greeks, it was not possible for private buildings to rival them.

Architecture, as applied to public purposes, began with the construction of temples; and till the time of the Persian wars or just before we hear of no other considerable public edifices. The number of temples remarkable for their architecture was till that time a limited one; although in the age just preceding the war with Persia this art had already produced some of its first works among the Greeks. In Greece itself the temple of Delphi was the most celebrated after it had been rebuilt by the Alcæonidæ. There was also the temple of Apollo in Delos. But it was about this time that the invention of the Ionic order by the Asiatic Greeks in addition to the Doric, which had been used till then, constituted a new epoch in the history of architecture. The splendid temple of Diana at Ephesus erected by the joint exertions of the cities and princes of Grecian Asia, was the first building in this new style. About the same time Polycrates built the temple of Juno in Samos. The temples which afterwards formed the glory of Greece, those of Athens on the Acropolis and elsewhere, were all erected after the Persian war. So too was the temple of Jupiter at Olympia. As to the temples in Lower Italy and Sicily, we can fix the epoch in which, if not all, yet the largest and most splendid of them, the chief temples of Agrigentum were erected; and that epoch is also subsequent to the Persian war. And if those of the ancient Doric order at Pæstum and Segestus belong to an earlier period, they cannot to one much earlier; as these cities themselves were founded so much later than those in Asia Minor. Just before and after the Persian war arose that prodigious emulation of the cities to make themselves famous for their temples, and this produced those masterpieces of architecture.

The other principal kinds of public buildings which were conspicuous for their splendour were the theatres, the places for musical exhibitions, the porticos and the gymnasia. Of the theatres, it has already been observed that they were erected subsequently to the Persian wars. The same is true of the halls for music. The porticos, those favourite places of resort to a people who lived so much in public, belonged in part to the temples, and in part surrounded the public squares. Of those in Athens, which by their works of art eventually eclipsed the rest, we know that they were not built till after the victory over the barbarians. Of all the public edifices, the gymnasia are those respecting which we have the fewest accounts. They were probably erected at a distance in the rear of the temples; though many of them were distinguished by excellent works of art.

This line of division, carefully drawn between domestic and public architecture by the Greeks, who regarded only the latter as possessing the rank of one of the fine arts, gives a new proof of their correct views of things. In buildings destined for dwellings, necessity and the art are in constant opposition. The latter desires in its works to execute some grand idea independent of the common wants of life; but a dwelling is intended to meet those very wants and is in no respect founded on an idea connected with beauty. The temples are dwellings also but the dwellings of the gods, and as these have no wants in their places of abode, the art finds here no obstacle to its inventions.

The plastic art and painting bore to each other, among the Greeks, the opposite relation to that which they have borne in modern times. The first was the most cultivated, and though the latter attained the rank of an independent art, it never was able to gain the superiority. It is not for us here to explain the causes of this; we need only mention one, which to us is the most interesting. The more public the arts are among any people the more naturally will the plastic art surpass that of painting. The works of both may be public and were so among the Greeks, but those of the former are far better suited for public monuments than those of the latter. The works of painting find their place only on walls; those of the plastic art existing entirely by themselves wherever there is room for them.

The works of the plastic art, statues and busts, were, in the times of which we speak (and among the Greeks, with a few limitations, even in subsequent times), only public works, that is, designed to be set up, not in private dwellings but in public places, temples, halls, market-places, gymnasia and theatres. I know of no one instance of a statue that belonged to a private man; and if there exists any example, it is an exception which confirms the general rule.* It may be said that it is only accidental that we know of no such instances. But if any taste of

* Demosthenes reproaches the wealthy Midias with his large house at Eleusis, which intercepted the light of others. Op. i. p. 565.

* Or can the anecdote be cited which Pausanias relates, p. i. 46, of the cunning of Phryne to gain possession of the god of love made by her lover Praxiteles? Even if it be true the fact is in our favour, for she consecrated it immediately as a public work of art in Thespiae, Athen. p. 591, in which city alone it was from that time to be seen. Cic. in Ver. ii. iv. 2.

that kind had prevailed at Athens we should find traces of it in the comedians and orators. If these are consulted in vain for such indications, we are justified in concluding that no such private tastes existed.

Phidias and his successors, till the Macedonian age, did not therefore labour to supply with their works the houses and collections of individuals. This by no means implies that they did not receive applications from private persons. If they had not the incredible multitude of statues which we have already mentioned could never have been made. This subject is so important that it demands to be treated of more at large.

The great masters were principally employed for the cities. These, or the men who were at their head (as the example of Pericles informs us), bespoke works of art or bought them ready made, to ornament the city and the public buildings. We have distinct evidence that the great masterpieces of Phidias, Praxiteles and Lysippus, owed their origin to this. Thus were produced the Jupiter at Olympia, the Minerva Polias at Athens by the first, the Venus at Cnidus as well as at Cos by the second, the Colossus of Rhodes by the third. Yet numerous as were the applications of cities, the immense multitude of statues could not be accounted for, unless the piety and the vanity of individuals had come to their assistance.

The first assisted by the votive offerings, of which all the celebrated temples were full. These were by no means always works of art but quite as often mere costly presents. Yet the collections of statues and pictures which belonged to those temples consisted, for the most part, of votive offerings.* But these were as often the tribute of gratitude from whole cities as from individuals.†

The vanity of individuals contributed to the same end by the custom of erecting statues, commonly of bronze, to the victors in the games.‡ When we remember the multitude of these games in Greece, the number of statues will become intelligible, especially of those of bronze, of which in many instances more than one cast was made; as the native cities of the victors would hardly fail in this manner to appropriate to themselves the fame of their citizens, which formed so much a subject of pride.

Painting, from its very nature, seems to have been more designed for private use. Yet in the age of Pericles, when the great masters in this art appeared in Athens, it was hardly less publicly applied than the art of sculpture. It was in the public porticos and temples that those masters, Polygnotus, Micon and others, exhibited the productions of their genius. No trace is to be found of celebrated private pictures in those times.§

Yet portrait-painting seems peculiarly to belong to private life. This branch of the art was certainly cultivated among the Greeks, but not till the Macedonian age. The likenesses of celebrated men were placed in the pictures which commemorated their actions; as that of Miltiades in the painting of the battle in the *Pœcile* or pictured hall in Athens; or the artists found a place for themselves or their mistresses in such public works.|| But properly speaking, portrait painting, as such, did not flourish till the times of Philip and Alexander, and was first practised in the school of Apelles. When powerful princes arose, curiosity or flattery desired to possess their likeness; the artists were most sure of receiving compensation for such labours, and private statues as well as pictures began to grow common, although in most cases something of ideal beauty was added to the resemblance.

We have ventured directly to assert that the arts in their flourishing period belonged exclusively to public life; and were not, according to the general opinion, which seems to have been silently adopted, divided between that and private life.

* Not to mention Olympia and Delphi again, we refer to the temple of Juno in Samos, Strab. xiv. p. 438, of Bacchus at Athens, Paus. i. 20. The temple of Diana at Ephesus was so rich in works of art that, according to Pliny, xxxvi. 14, a description of them would have filled several volumes.

† The temples received such presents not only during the lifetime of the donors but as legacies. A remarkable instance of this is found in the will of Conon, who left 5,000 pieces of gold (*σφαίρες*) for that purpose. Lys. Or. Gr. v. p. 639.

‡ See the passage in Pliny, xxiv. 9. His remark that a statue was erected in honour of every victor at Olympia seems hardly credible. Cf. Paus. vi. p. 452.

§ It is true Andocides reproached Alcibiades in his oration against him of having shut up a painter who was painting his house, Or. Gr. iv. p. 119. But this was not the way to obtain a fine specimen of the art. Allusion is there made to the painting of the whole house, not of an isolated work of art; and we are not disposed to deny that in the times of Alcibiades it was usual to decorate the walls with paintings. On the contrary, this was then very common, for the very painter Archagathus gives as his excuse that he had already contracted to work for several others. But these common paintings are not to be compared with those in the temples and porticos; which, as Böttiger has proved, Ideen, &c., s. 282, were painted, not on the walls, but on wood.

|| Polygnotus, *e.g.* introduced the beautiful Elpinice, the daughter of Miltiades, as Laodice. Plut. iii. p. 178.

Be it remembered this is to be understood only of works of art in the proper sense of the expression; that is, of those which had no other object but to be works of art; of statues, therefore, and pictures; not of all kinds of sculpture and painting. That the arts connected with private wants were applied to objects of domestic life, to articles of household furniture, to candelabra, vases, tapestry and garments, will be denied by no one who is acquainted with antiquity.

It was not till a Lucullus, a Verres and others among the Romans had gratified their taste as amateurs, that the arts were introduced into private life, and yet even in Rome an Agrippa could propose to restore to the public all the treasures of the arts which lay buried in the villas. We should not therefore be astonished if under such circumstances the ancient destination of arts among the Greeks should have been changed, and they should have so far degenerated as to become the means of gratifying the luxury of individuals. And yet this never took place. This can be proved as well of the mother country as of the richest of the colonies.

Pausanias in the second century after the Christian era, travelled through all Greece and saw and described all the works of art which existed there. And yet I know of no one instance in all Pausanias of a work of art belonging to a private man, much less of whole collections. Everything was in his day, as before, public in the temples, porticos and squares. If private persons had possessed works of art who would have prevented his describing them?

Verres plundered Sicily of its treasures in the arts wherever he could find them, and his accusers will hardly be suspected of having concealed anything. But in this accusation, with one single exception,* none but public works of art are mentioned. What shall we infer from this but that no considerable productions of the fine arts were possessed by private persons in Sicily?

So deeply therefore was the idea fixed among the Greeks that the works of the artists were public, that it could not be eradicated even by the profanations of the Romans. And this is the chief cause of their flourishing. They thus fulfilled their destiny; belonging not to individuals but to cultivated humanity. They should constitute a common property. Even in our times, when individuals are permitted to possess them, censure is incurred if others are not allowed to enjoy them. But even where this privilege is conceded, it is not a matter of indifference whether an individual or the nation is the possessor. The respect shown to the arts by the nation in possessing their productions confers a higher value on their labours. How much more honoured does the artist feel, how much more freely does he breathe when he knows that he is exerting himself for a nation which will esteem its glory increased by his works, instead of toiling for the money and the caprices of individuals?

Such was the condition of the arts in Greece. When emulation arose among the cities to be distinguished by possessing works of art, a field was opened for a Phidias and Polygnotus, for a Praxiteles and Parrhasius. They were better rewarded by glory than by money; some of them never worked for pay.† Need we then add any further remarks to explain why the fine arts declined with liberty? Philip and Alexander still saw a Lysippus and an Apelles, but with them ends the series of creative minds such as no other nation has ever produced.

But the taste of the nation for the arts and their productions did not end with those artists. They had taken too good care to perpetuate that fondness. When the Grecians had lost almost everything else they were still proud of their works of art. This excited even in the Romans respect and admiration. "These works of art, these statues, these pictures," says Cicero, "delight the Greeks beyond everything. From their complaints you may learn that that is most bitter to them which to us appears perhaps trivial and easy to be borne. Of all acts of oppression and injustice which foreigners and allies in these times have been obliged to endure, nothing has been more hard for the Grecians to bear than this plundering of their temples and cities."

* Namely, the four statues which he took from Heius. Cic. in Verrem, ii. iv. 2. Yet they stood in a chapel (*sacrarium*), and were therefore in a certain measure public. The name of Heius seems, however, to betray that the family was not of Grecian origin. But what does one such exception and in such an age prove respecting an earlier period?

† Polygnotus painted the *Pœcile* for nothing; Zeuxis, in the last part of his life, would receive no pay for his pictures, but gave them away. Pliny, xxxv. 36. Thus a partial answer is given to the question how the cities could support the great expense for works of art. Besides, in Greece as in Italy, the works of the great masters did not become dear till after their death. The little which we know of their personal condition and circumstances, represents them for the most part as men of fine feelings and good fellowship who, like the divine Raphael and Correggio, in the moments sacred to mental exertion, raised themselves above human nature, but otherwise enjoyed life without troubling themselves much about money. Phidias for all his masterpieces did not receive a third part as much as Gorgias for his declamations.

We have thus far endeavoured to consider Greece from all the points in which she made herself glorious as a nation. Who is it, we may finally ask, that conferred upon her her immortality? Was it her generals and men of power alone, or was it equally her sages, her poets and her artists? The voice of ages has decided, and posterity justly places the images of these heroes of peace by the side of those of warriors and kings.

SOCIETY OF ANTIQUARIES OF SCOTLAND.

AT the monthly meeting, Mr. T. G. Law presiding, Dr. Christison, secretary, called attention to the subject of the geographical distribution of certain place names in Scotland—a subject which he believed would yield results of great importance in their bearings on philology and early history. As the basis of such a study a complete list of Scottish place names was necessary, and such a list did exist in the Ordnance Survey Office, but inaccessible to the scientific investigator, who was thus compelled laboriously to re-collect for himself materials which a comparatively small outlay for printing on the part of the Government might have placed within the reach of everyone desirous of utilising them. He had taken his materials from the 1-inch maps and divided them into three sections, according as they implied elevation, depression and situation or habitation. Of those implying elevation the word Ben, which was most frequent in the Highlands, occurred only in that part of the south of Scotland comprised in the hilly region of South Ayrshire and North Galloway, where it is pretty frequent, though it only occurs twice in Dumfries and once in Peebles, but disappears entirely in the Lammermoor and Cheviot ranges further east, and reappears again in the Ochils. Pen, on the other hand, as a hill name, is less frequent south of the Forth, and scarcely appears in the south-west corner of Scotland, where the Bens are clustered, while north of the Forth and outside of the Highlands it seems entirely absent. Dun, in its various significations and forms, is more widely, though unequally distributed, though almost absent in Orkney and Shetland. Fiold or field, unlike most other hill-roots, is almost always an affix, and the great home of the Fells, which is the most common form of the word, is in the south-west of Scotland. In the Hebrides it usually takes the form Val or Bhal. Bar is confined mostly to hills of low elevation, and is most frequent in Galloway, Ayr and Argyll, but in the whole of Eastern Scotland north of the Firth it scarcely appears. With regard to the roots implying depression, and applied to glens and streams, while Dal or dale was widely spread, as being derived both from Norse and Saxon, the central hill region of Peebles and Selkirk is the great home of the “hopes,” while “gill” is rarely found in the Highlands, but widely spread in Orkney, Shetland, Skye, Arran, and in Dumfries, Peebles, Lanark and Galloway, though its comparative infrequency in the Hebrides is remarkable. Lane, signifying a brook, is almost confined to the hill country round Loch Doon, from which they radiate into Ayr, Dumfries and Galloway, while “grain,” meaning a stream, is most frequent in Dumfries, and “beck” is most confined to Annandale. The paper concluded with a comparison of the distribution of the names Bal and Pit, applied to habitations, the latter of which though widely distributed to the north of the Forth scarcely appeared on the southern side of the Firth. After referring to the works of Sir Herbert Maxwell on the place names of Galloway, Professor Mackinnon’s articles on those of Argyllshire, he recommended the prosecution of the study so as to include the whole of Scotland.

Rev. J. King Hewison, F.S.A.Scot., Rothesay, described the numerous prehistoric forts of the island of Bute. These were sometimes of earth and sometimes of stones, and were mostly now very much destroyed. In Dun Sculpsay the doorway could yet be discerned, and near it is a promontory cut off from the land by fosse and fortified. All the stone forts have very thick walls, and some are vitrified. Dun Burgadal has its walls still standing 6 feet high, the wall being 14 feet in thickness. It has a gallery in the thickness of the wall. Dunagail, however, is the most important of the forts in Bute. Its gateway is distinguishable and its walls have been vitrified. The wall is 285 feet in length and at least 6 feet in thickness, and the stones are rather unequally vitrified. In one place the vitrification extends almost to the whole of the wall, which is at that part 5 feet 6 inches in thickness. The Fort of Islandbuie is also vitrified. Its remarkable feature is that it has round its oval outline the stances of four towers 14 feet in diameter at the four cardinal points. The number and importance of the forts in the island indicated a large population in early times.

Mr. George F. Black, assistant keeper of the museum, gave an account of Scottish amulets and charm-stones, of which a large loan collection from many different parts of the country were exhibited. The object of the paper was to describe in detail all the known Scottish specimens, which are much more numerous than could have been gathered from the existing literature of the subject. Some are balls of rock crystal, like

the Clach Dearg of Ardvourlich and the Clach na Bratach of the Robertsons of Struan, previously described by Sir James Simpson. Others are balls of stone, like that of the Bairds of Auchmeddan, and others are flint arrow-heads mounted in silver or pewter. The prehistoric beads called adder-beads and other varieties of personal ornaments not so very ancient, such as Luckenbooth brooches and whorls of stone, were credited with many virtues, and used in various ways to cure disease or avert the evil eye. The seeds of a West Indian plant wafted across the Atlantic and cast ashore on the coasts of the Hebrides were also mounted in silver and used as charms, one being shown which had been used for 200 years, and held in high repute for alleviating the pains of labour. The Cowan’s Taid-stane from Stirling and Barbreck’s bone from Argyllshire were noted charms, the latter famed for curing madness, and so highly valued that a deposit of 100*l.* sterling has been known to have been made as security when it was borrowed.

SIR JOHN GILBERT’S PICTURES.

THE *Birmingham Post* says the Mayor of Birmingham has received the following letter from Sir John Gilbert, P.R.W.S.:—“Vanbrugh Park Road, West Blackheath, London, Thursday, April 6, 1893. To the Worshipful the Mayor of Birmingham. Dear sir,—I have for some years past ceased to part with every picture I have painted, both in oil and water-colour, with the idea of building a gallery for their reception and giving them to the public; since which I have thought out another course of proceeding. Taking into consideration the permanent art galleries, especially those of the great cities of London, Birmingham, Liverpool and Manchester, and the lead which they have taken in all matters of art, I have determined to offer my collection to those galleries as a free gift. There are fifteen or more oil-paintings, some of considerable size, in perfect and pure condition and in handsome frames, and many water-colour pictures also framed. If possible, I should wish them in each case to be placed together. This matter, however, and other minor considerations, could be arranged afterwards. All these pictures have been exhibited at the Royal Academy and in the galleries of the Royal Society of Painters in Water-Colours, Pall Mall East, of which society I am president. A portion of my collection I beg to offer to the city of Birmingham Art Gallery. I am not well, and am dependent upon another for writing this for me.—I have the honour to be, your obedient servant, John Gilbert.” The Mayor has written to Sir John Gilbert accepting his offer, and expressing the gratification it will afford him to communicate it to the Council.

Sir John Gilbert, R.A., president of the Royal Society of Painters in Water Colours, lives, the *Westminster Gazette* says, in a roomy, old-fashioned house at Vanbrugh Park, on the borders of Greenwich Park. The house is literally crowded with pictures from Sir John’s brush, and these are all to be given to the nation.

“When I have finished,” the old artist said to a representative, “the house will be completely denuded. You know I have refused for the last dozen years or so to sell any of my pictures. I intended to possibly place them all in some gallery of my own, but that, I find, would be too much trouble. I want to see them hung properly before I die, so that is why I have offered my pictures without reservation to the various corporations.”

As I reached the house, the representative writes, members of the Corporation of London were driving away. I asked Sir John what was to be sent to the Guildhall. The artist pointed out the principal pictures to me. All have been exhibited, I believe, either at the Royal Academy or at the Water-Colour exhibitions. A cursory glance showed pictures bearing such far-apart dates as 1838 and 1891.

The Guildhall will ere long, Sir John told me, be enriched by such well-known pictures as his *St. George and the Dragon*, painted in 1880-81; *Henry VIII. and Cardinal Wolsey* (the scene taken from Shakespeare), painted in 1888; *Lancelot*, painted in 1886; and *Quixote’s Niece and Housekeeper*, painted in 1891. All these are in oils. Then in water-colours Sir John is going to give Londoners *Cardinal Wolsey on his way to Westminster Hall*, painted in 1886-87; *The Battle of the Standard*, painted in 1879-80; *The Knight Errant*, *The Witch* (a girl on a white horse), *War*, and *The Prince and Princess of Wales going to a Drawing-room*—all the work of recent years. Sir John Gilbert smiled as I recalled his popular style, “the Scott of painting,” but in answer to my query as to which picture he considered his best, he replied that he was unable to say—all were characteristic of him. With reference to the benefactions to provincial galleries, Sir John has not yet decided what gifts he will make to the Liverpool and Manchester Corporations. The former body, with commendable enterprise, had already sent a representative to Blackheath. By this time the artist’s friends were fearing lest he should over-weary himself, as he is unfortunately not in the best of health.

JACQUES LOUIS DAVID.

IT was only equitable that as Jacques Louis David had created a revolution in art, he also should in his turn be set aside. There was never an artist who was inspired by loftier ideas. He sought to recreate the heroic period of Greece and Rome in France, for he believed his countrymen were the legitimate heirs of the great men of antiquity; but during his lifetime he was compelled to see that his efforts were without avail. Frenchmen grew tired of posing as antique heroes, and although there must always be a close union between classicism and academicism in France, yet David's system became obsolete as soon as the Restoration took place. His career is, however, worth recalling.

David was born at Paris in 1750. At that period Boucher and his school still reigned in France. Success was certain to those who followed the beaten track. David quitted it, and, protesting against the taste of his masters and of the public, dared to study Poussin. The sight of the pictures which were then the fashion produced on him the same effect that *lettres de cachet* and the abuses of Government produced on Mirabeau—it inflamed him with the wish for a revolution. Accordingly, when Vien had given the signal of reform, and exhibited in his works a new style, David, eagerly following his steps, and it may be said appropriating his ideas, speedily found himself at the head of the reformers of art.

He had the qualities of the chief of a school: an ardent and enthusiastic temper, an energetic will. Unfortunately, to this soul of an artist was added the spirit of a logician. To constitute an accomplished painter, no doubt the force and power of a Michel Angelo are above all things necessary; but, in order to guide that force and that power, there ought to be a mind open to all ideas, fond of nature as she really is, observant but devoid of system; in short, such a mind as that of Leonardo da Vinci. David, on the contrary, was endowed with one of those intellects which are more vigorous than extensive, which are capable of a lively conception of things, but on the condition of embracing only a limited number of them, and which, having once adopted any action, are absorbed by it, and pursue it to its last consequences without taking the trouble to inquire whether or not it is consonant to truth. All that his mind was capable of conceiving, David had the gift of expressing on canvas with the superiority of genius. Hence the surprising beauties which strike us in his pictures. But his mind was not capable of conceiving enough. Hence his finest works are incomplete, cold, inanimate. Such a mind, united with such a temper, must of necessity produce a fanatic in politics, a mannerist in the arts. In the hall of the convention as well as in his painting-room the feelings of David were continually the dupes of his reason.

What had struck him most forcibly in the painters whom he wished to dethrone was their incorrectness of drawing, and their systematic inattention to the human form. Pretending to be faithful to nature, they were guided only by fashion. All their mouths smiled and all their noses turned up. The disposition of David's character naturally drove him into the other extreme. From the moment that he began to attend to form he thought of nothing else. With the soul within, with that internal power of which form is only the envelope and the manifestation, he did not trouble himself. "The body of man is the whole man," was his motto. Very soon Poussin did not satisfy him; he must have something more decided, more absolute. The ancient statues attracted his notice. In them he discovered that purity of line and contour, that beauty, altogether external, to which he aspired; and thenceforward, without disturbing himself to inquire if the real object of the art was not escaping him, he endeavoured to make his pencil the rival of the Greek chisel.

This is not to say that he abstained from the study of nature. Long and painful labour had disclosed to him all the secrets of anatomy; he constantly painted in the presence of living models, but these studies were not made by him for their intrinsic value. Nature never seemed to him to be an authority entitled to all his confidence; she was too various, too changeable. Even while affecting to imitate her, he subjected her to the control of those abstract types which he regarded as forming the law of beauty. A strict adherence to nature, he was apprehensive, might betray him into that arbitrary and capricious style of design with which his predecessors were justly reproachable. His mind could find no repose but in some predominating idea, in some system, or in the centre of feelings and doctrines. This explains the defective manner in which he saw nature; he studied her only as she contributed to, and never when she contradicted, his system.

Having entered on this new path, all his powers were concentrated in a single point. David arrived at his object with giant strides; his first efforts were most masterly, all the innovations which he had been meditating he realised at once, and carried them to the highest perfection. The *Horatii*, the

Brutus, the *Belisarius*, are finished models of that simple and severe style, of that dignified design of which, until the period of their production, antiquity alone had exhibited any example. It is impossible to convey any notion of the enthusiasm with which these *chefs-d'œuvre* were received. At another period, perhaps, the admiration which they excited would have been mixed with censure; but at the time at which they made their appearance the public mind was not in a condition to love or hate by halves; exclusive in politics, it was exclusive in everything else. Delighted with David for the kind of beauty which he had elicited, critics declared that it was the true beauty—that it was the only beauty. Good taste seemed to have been recovered, and the golden age of painting to be about to be renewed; a sort of idolatry for ancient forms possessed every one—it was one of the crises of the Revolution. It may be imagined with what unanimous contempt the works of those unfortunate painters were treated which were before the objects of general admiration; they were devoted to public indignation, with all the rest of the ancient régime; and yet in those tasteless compositions, if there was no real merit, at least there was a good intention, which ought never to be despised—the intention of imitating life. No consideration, however, could rescue them from their fate. Even the Italian painters, who had been banished to the garrets ever since the times of the Marchioness of Pompadour, did not gain much by this reaction. Some admirers they certainly found among the persons who had just been reading Lessing's "Laocoon," or who instinctively felt that the laws of painting and the laws of sculpture were not exactly the same, but in general their beauties were in little estimation—"they had not sufficiently studied the antique."

Now that we are more tranquil, that we feel the imperfection of former systems, and begin to understand that a country may be a republic without the assumption of Roman names and habits, and that the beauty of the antique is not the only possible beauty, David's pictures have, in some degree, lost one of their merits—the merit of circumstances. Nevertheless, such is the power of the hand by which they were created that it is impossible to contemplate them without that feeling of respect which is inspired by all works of genius. We cannot sympathise with beings whose features seem incapable of human emotion; we cannot but remark in the way in which they are disposed something too symmetrical, too analogous to the grouping of a bas-relief; but it is impossible (unless we are prejudiced by the opposite system) not to be struck with the harmony of all the parts, with the unity of conception which manifests itself in the smallest details, with the forms, ideal it is true, but having reference to a pure and perfect type. The pleasure with which a picture by David is contemplated is of that rational kind which accompanies the perusal of a Classic tragedy. In either case the work ought to be regarded in the point of view in which the author intended it to be regarded. If you stop before the *Horatii* or before the *Sabines*, just after having been looking at a head by Guido, or a Madonna by Correggio, all that portion of your soul which has been powerfully excited by the animated and passionate expression of the Italian painter will find nothing to interest it; you will feel frozen; in vain will reason call on you to admire the beauties which it has produced; you will exclaim, "These pictures have no expression," and you will pass by with disdain. But turn your eyes from nature, such as she is; dream, as David did, of beings colder, more severe, less impassioned than human; imagine that this *Horatii*, this *Brutus*, this *Leonidas*, were discovered amidst the ashes of Herculaneum—and then, having become less urinous in your demand, you will become more just; you will admire the beauties which the absence of other beauties prevented you from sooner observing.

It is only in this way that we can fairly judge of men who have employed their genius in the service of a system. It is thus that Alfieri must be read; it is thus that we must listen to the music of Glück. Alfieri, Glück and David, three great artists, three powerful minds, must nevertheless be admired for qualities somewhat foreign to the arts which they cultivated. Glück often said, "When I compose, I endeavour to forget that I am a musician." It was not music, but declamation which he wished to produce. Alfieri, although a dramatic writer, was jealous only of the title of a poet or a thinker. David, likewise, seems sometimes to have exclaimed with Glück, "Let me forget that I am a painter."

After all, however, we shall ill appreciate David's talent if we believe that he was invariably the slave of his system. He excelled in certain kinds of expression. No one has represented better than he the reflecting courage, the strength of mind, which shows itself in the warrior seated on the left of Leonidas. And in the picture of the *Sabines* what can be more graceful and more animated than the group of children? What can be more sweet and more tender than the daughters of Brutus? He has proved also that he was capable of quitting ideal nature: witness his magnificent design of *The Oath of the Tennis Court* and, above all, the clerical group in the picture of *The Coronation*, in which the Pope and all the ecclesiastics

who surround him are absolutely alive. It is nature taken in the fact.

After his banishment David gave his talent a new direction, and turned his attention to colouring. On the two pictures which he sent to France, *Cupid and Psyche* and *Mars and Venus*, he may be said to have lavished all the riches of the Venetian palette. But, according to the custom of exclusive minds, he acquired one quality only by the loss of another. These two pictures do not everywhere possess the severe taste and the pure and elegant drawing of the author of the *Horatii* and *Leonidas*.

Although absent from Paris, David during his life preserved a sort of empire over the school of painting. French artists, indeed, every day made attempts to pass the line which he had traced for them, but his name was still venerated. Among his pupils were Lathière, who was for ten years director of the Academy at Rome, and who with all his power endeavoured to make David's principles prevail in France; Drouais, who might have been the best exemplar of the school, but he died in his twenty-fifth year; Gros, who vacillated between David's style and romanticism; and Gerard, who preferred French to Roman history.

CHURCH BUILDING IN IRELAND.

THE erection of a church suitable to the requirements of the prosperous and improving town of Nenagh has been in contemplation for a considerable period of time, the present edifice being a queer old relic of penal times, situated in an out-of-the-way, damp, low-lying locality, most inconvenient of approach, and in every way unsuitable. Years ago the late Dr. Flannery, bishop of the diocese, conceived the idea of converting the old Norman donjon tower of the Butlers, known as "Nenagh Round," into a belfry, with the intention of building a church alongside of it. A storey was added to the tower, in bad keeping; but, apparently, it never was roofed, and the project of erecting the church remained in abeyance. The present pastor, Dr. White, on his appointment to the parish, set to work. A collection was started, a site acquired, and the foundation-stone was laid in due course. Subsequently competitive designs were invited from four architects, well known in connection with ecclesiastical works. As a result two designs described by expert authority as of exceptional merit were laid before a committee of selection consisting of Dr. McRedmond and Rev. Dr. White, with the president of the Royal Institute of the Architects of Ireland, Mr. Thomas Drew, R.H.A., acting as professional assessor. This gentleman drafted the "conditions of competition," which were of an unusually stringent character, and his estimate of the comparative merits of the plans was submitted in a comprehensive report. The condition of anonymity was observed, the plans not being identified by even the usual motto, but instead were distinguished respectively by the referee himself as "No. 1 'Red' plan," "No. 2 'Black' plan." Mr. Drew opens by congratulating those interested in building a fine church for the town on the worthy response to their invitation by the tender of two masterly designs for a noble church, with the thought, care and skill bestowed on splendid draftsmanship in setting them worthily before them. He considered that in ritual fitness there was little to choose between the two, but that in architectural treatment, however, there was very marked and characteristic divergence. Both designs were capable of erection for the amount named, viz. 20,000*l.*, but the referee held that neither gave sufficient floor, but the successful competitor has fully succeeded in satisfying his committee on the point. No. 1, he says, is the perfection of that fine type of Catholic church developed in Ireland during the later part of this century. While bearing a resemblance to others, this appears to surpass most in architectural study and completeness. The referee proceeds with his review of the other design as follows:—"May I, however, not be deemed inconsistent in saying that my personal sentiment and preference are with No. 2. I have said that in disposition and convenience for ritual both designs are very similar, and, therefore, on all fours in that respect. The attractiveness for me in No. 2 lies in its recurrence to more ancient and traditional treatment of style than obtains usually in modern church building, and to which my sympathies and sentiment lean. I like this design for its quality and reflection of the grand Cistercian school of the thirteenth century in these countries. I prefer its square-ended sanctuary as more native in tradition, and an agreeable variety from the more foreign apsidal one which, however beautiful in itself, appears to me to be becoming accepted and invariable in Ireland. I like the superior massiveness of walls and piers, suggestive of old and noble work; I like the simplicity and dignity of features imitated from the old Cistercian manner; I prefer the long drawn effect of a five-bayed nave to a four-bayed one. The tower, too, *per se*, is, I think, a better composition than that of No. 1. If two churches were erected according to these designs I could cordially admire both for separate qualities, but I should linger longest and with most personal gratification with No. 2." Then

he proceeds to say that sentiment should not weigh with him in the selection of a design, but that perhaps it might weigh with those for whom the church was to be erected; that they were, therefore, free to choose, on the one hand the modern type of church, or on the other hand the revival of an older style. The result was the selection of the design of Mr. Walter Doolin, M.A., architect, Dublin, to whom the execution of the work has been entrusted.

BRITISH INSTITUTE OF PUBLIC HEALTH.

EXAMINATIONS for sanitary inspectors were held by the British Institute of Public Health on the 7th and 8th inst., in the State Medicine Department, King's College, London. The examinations were arranged as follows:—Friday afternoon, preliminary examination in composition, arithmetic, &c.; Friday evening, written examination in building construction, chemistry and physics in relation to sanitary work, legal enactments, and general duties of inspectors; Saturday morning, inspection of two houses, and candidates' reports thereon; Saturday afternoon, oral examination. The examiners were S. R. Lovett, L.R.C.P., medical officer of health, St. Giles, president of Metropolitan Branch of Society of Medical Officers of Health; Dr. B. H. Murby, M.D., D.P.H., medical officer of health and public analyst, Portsmouth; Professor Bannister Fletcher, F.R.I.B.A.; H. Mansfield Robinson, LL.D., vestry clerk, Shoreditch, and chairman; Professor W. R. Smith, M.D., D.Sc., medical officer of health and public analyst, Woolwich. The report of the examiners will be presented to the Council of the Institute at its next meeting.

MR. VICAT COLE, R.A.

THE death is announced of Mr. Vicat Cole on Thursday, the 6th inst., at his residence at Little Campden House, from sudden failure of the heart's action. The *Daily News* says:—Only last Sunday he was showing his picture to his friends—the picture we shall all look at with mournful interest when the exhibition opens. His loss indeed is great, and in a sense one not likely to be replaced. Alike in his sympathies and his subjects, he was thoroughly English. He loved the landscape which he studied so carefully and painted so well. No artist of this generation has given us, as he has done, its thoroughly sunny character, the leafiness of its woods, the fat luxuriance of its meadows, the richness of its grain fields, the bushy beauty of its hedgerows, the security and the picturesqueness of its homesteads. His earlier work gave no promise of this achievement. The dry metallic art of Creswick and of Lee was there as an influence in his student days, and he learned, from their work, as indeed from his own father's, what it had to teach him, but he soon emancipated himself from these restraining models, and his popularity was immediate. Year after year in those old rooms, on the north side of Trafalgar Square, he exhibited his Surrey cornfields, with their yellow grain ripening in the blaze of the sunshine, or gave us a bend of the Thames, with the tall poplars and the smooth water above the weir. Half the secret of his popularity was his sincerity. He was always impressed by his subject, and he painted it "as though he loved it." And in his work he spared neither pains nor time. He was not what was called "clever;" there is no smartness in his work. He was too thorough to be clever, and therefore he was no considerable producer. He was always at his work, and yet there is not much of it to represent an art life which began at twenty—began, indeed, at eighteen, for his first exhibited work was in 1851—and continued without interruption for forty years; for Vicat Cole never considered the market. His popularity for the last thirty years was such that he could readily have got commissions for twice as much as he painted. He had a Londoner's partiality for the Thames. He knew the river from above Oxford, where it is a stream, to below London Bridge, where it widens into the Pool. And he knew its boats and its shipping off by heart—its gay-coloured lighters, its barges, loaded to the brink of the muddy water, its steam-tugs, darting mischievously about, its great ocean-going liners—he painted them all with the knowledge of a craftsman. It was his boast that he had been in a way the biographer of the great river. When he was sending *The Pool* to the Academy in 1888 he told the writer that it would be the last of the series. He had painted Richmond and Abingdon, and Wargrave and Streatley. But the temptation was too strong, and two years afterwards another great canvas was devoted to another great Thames subject, and it is a third Thames subject, a view off Greenwich, which this year received the last touches of his brush. It is curious that though he travelled a great deal and went over some of the ground which Turner had trod before him, it was always the Thames or the home landscape woods on the Arun or the slopes of Leith Hill which had for him a paramount attraction. He painted the Alps at Rosenlani and Marienburg on the Moselle, as he also painted Loch Scavaig in the Isle of

Skye, but there was not the feeling in these works which he knew so well to put into his Surrey pastorals and his autumn woods. Mr. Ruskin wrote of his *Richmond Hill* that some passages of subdued light seen under the trees were, in their studied perfection, about the most masterly things in landscape work in the whole exhibition. That was the exhibition of 1875, to which he also sent his *Iffley Mill*. Fifteen years before he had sent his first picture to the Academy; in 1870 he was elected associate, and ten years later attained the full honours of membership. Mr. Cole was but sixty years of age.

National Society for Checking the Abuses of Public Advertising.

SIR,—The disfiguring effect of certain forms of public advertising and the rapid growth of the evil have of late formed the subject of complaint and suggestion in many organs of public opinion. It may interest many of your readers to know that a society has been formed with the object of checking the abuses in question, and generally of protecting and promoting the picturesque simplicity of rural and river scenes and the dignity and propriety of our large towns.

Although it is hoped that all persons who are in general sympathy with the purpose will become members, it is provided that no person is committed to each and every feature of the scheme. The subscription is 2s. 6d. per annum, and the services of all the officers are honorary. The measures contemplated—subject always to the result of closer examination and more mature consideration—include:—

1. Such an amendment of the existing law as would confer on local representative bodies effective control over all forms of painted or printed announcements visible from the thoroughfares or public places, and would direct them to frame reasonable regulations, the regulations framed in pursuance of these powers not being necessarily uniform over the whole area, but varying according to the special character of distinct localities. In case of breach of the regulations relief to be obtainable on complaint of aggrieved persons. It is impossible to lay down beforehand any hard and fast rule as to the degree of prohibition. But no doubt it would be easy in many localities to secure a veto on sky signs, advertisements on chimneys and towers and parapets, hoardings and boards in fields, straggling posters and tablets on walls, gigantic hoardings, the more glaring defacements on town sites of particular historical or architectural interest or at picturesque rural spots—the sort of intrusions, in short, which the Laodicean judgment pronounces offensive. The “invasion of the country” by the defacer is felt by nearly everyone to be an outrage, and to repel it would involve the minimum of trouble and afford the maximum of relief.

2. The insertion in all bills giving legislative authority for the acquisition of land or construction of works of provisions either prohibiting or subjecting to appropriate regulation (as the case may require) the use of any portion of the fabrics for advertising purposes.

3. A common understanding that the members will each at his own discretion abstain (as far as may be) from using commodities which he personally feels are advertised in an offensive way, or patronising establishments which he regards as exceptionally unscrupulous in advertising display.

4. The policy of imposing a duty or special rate on all exposed advertisements as a form of local or Imperial revenue is under consideration.

Further particulars of the Society's plans with list of members may be obtained by written application to Richardson Evans, 1 Camp View, Wimbledon Common.—We are, &c.,

A. WATERHOUSE.	

Politics in Relation to Business.

SIR,—In last week's *Architect* was some allusion to the effect of political disturbance on architects' business in Ireland. Most architects I know are but now realising that it is absolute paralysis of their business. In my own and other offices, one by one, each and every undertaking started this season has been postponed or abandoned, an experience absolutely unprecedented. It seems strange to anyone who has lived a busy hurried life for thirty years to come to an office where no work is to be done, no correspondence to be read, and no callers. It is so in the general run of architects' offices. Business had been “drying-up” somewhat in anticipation during last year. With the introduction of the Bill has come collapse

of business, except to those of the profession who have a special corner in Roman Catholic church or convent building. The loss to the wage-earning class connected with building in Dublin will probably represent in the coming year not less than 100,000l. I estimate this from the amount of coming work abandoned in the last few weeks.—Yours faithfully,

ARCHITECT.

[The above letter has been received from one of the principal architects in Ireland.—ED.]

The Architectural Association.

SIR,—May we be allowed to remind your student readers that the lectures on “Professional Practice,” by Mr. Edwin T. Hall, F.R.I.B.A., commence on April 18, and Mr. F. W. Pomeroy's class on modelling on April 20? We shall be glad to receive as soon as possible the name of those desiring to enter, so that the necessary arrangements may be made.—Yours faithfully,

EDWIN S. GALE

F. T. W. GOLDSMITH

Hon. Secs.

56 Great Marlborough Street, W.: April 11.

GENERAL.

A Committee has been appointed to arrange for the holding of an exhibition of works in black-and-white at the Leeds Fine Art Gallery in the autumn.

The Mersey and Irwell Joint Committee have appointed Sir Henry Roscoe chemical adviser to the committee for twelve months, at a salary of 700l.

Mr. G. Fox, architect, Dewsbury, has been instructed to prepare plans for four cottage homes, at a cost of 550l. each, for children under the charge of the Dewsbury Guardians.

Mr. Lewis F. Day will deliver the second of the series of the Cantor lectures, “Some Masters of Ornament,” at the Society of Arts, on Monday, the 17th inst.

The Emperor of Germany will present the King of Italy with a statuette, modelled by Professor Begas, and representing a woman holding a shield bearing the motto “Savoya sempre avanti.”

Prudhon's *Saisons*, out of the Denain collection, have been sold in Paris for 80,000 francs, a portrait by Nattier for 42,700 francs, and one by Rembrandt for 41,000 francs.

Tintoretto's *Portrait of an Italian Nobleman* in the Doge's Palace, Venice, has been injured by some mischievous person. It was valued at 10,000l.

Alderman Gamble has presented to the Town Council of St. Helen's a plot of 1,500 square yards of land, with a sum of 20,000l., for the erection of a central library and reading-room and a school for technical education and manual instruction.

Mr. G. Herbert Strutt, of Milford, has sent a cheque for 4,000l. to the building fund of the Derbyshire Royal Infirmary, in addition to 1,000l. previously given by him for the same object.

Mr. Whitworth Wallis, the keeper of the Birmingham Art Gallery, has, says the *Birmingham Post*, reported to the Purchase Committee that he has inspected in Paris the Spitzer collection of objects of industrial art, and has selected certain specimens as worthy of being acquired for the Gallery. The committee authorised Mr. Wallis to negotiate for their purchase at prices which he named to the committee as in his opinion reasonable. The specimens in question are chiefly examples of the metal work of various nations.

M. Didier Debut, the French sculptor, died on Wednesday, the 5th inst., at the age of sixty-nine. He was a pupil of David d'Angers, and was the sculptor of a number of public works in Paris, including the statue of Ledru-Rollin and the caryatides of the Tribunal de Commerce.

Mr. A. McGibbon, president, at the monthly meeting of the Glasgow Architectural Association, Mr. A. N. Paterson, vice-president in the chair, delivered a lecture to the members under the title of “Some Minor Practical Building Details.” Interesting and instructive instructions were given on the many different items regarding principles of construction in connection with masonry, carpentry and joinery, iron work, &c.

Mr. John Malcolm, of Poltalloch, has presented to the British Museum an illuminated manuscript which the authorities endeavoured to purchase some years ago for 2,000l. It is a “Book of Hours,” illustrated with full-page miniatures by artists of the Milanese school between the years 1490 and 1520.

The Course of Lessons in modelling at the Royal Academy School of Architecture is terminated for the session, and a course of eight demonstrations will be given by Mr. Stannus, on Mondays and Thursdays at 6.15 P.M., commencing on Monday, the 17th inst., on “Sub-paneling and Ceiling-design.”

The Annual General Meeting of the London and Lancashire Fire Insurance Company will be held at 12 o'clock noon, on Thursday, April 27, at the Law Association Rooms, Cook Street, Liverpool.

The Architect.

THE WEEK.

DURING the preliminary stages of the Hull Trades Union case we advised the plaintiff not to be sanguine of success, for it is well known that the leaders of workmen have generally succeeded in wriggling out of the consequences of their acts. We could not have known that in Hull there was little astuteness displayed, and that the defendants were so presumptuous as to dictate who were to supply the materials that were to be used in the buildings on which the members of the trades unions were employed. It was not merely a case of ordering men to cease to work for an obnoxious employer. If the societies had been satisfied with calling out the workmen who were engaged on the buildings for which MYERS & TEMPERTON had obtained the contracts the courts could not interfere, but they insisted that it was penal to supply the firm with bricks, artificial stone, lime, &c., and because the plaintiff in the action declined to obey the unionist dictation and to leave his brother in the lurch, an effort was made to prevent all builders in the Hull district from dealing with him. The terrorism of the system is oppressive, and it was proved that people who had entered into contracts with the plaintiff preferred to accept the consequences of breaking them rather than come into collision with the Hull unionists. The fines that have been inflicted and the costs will, of course, come out of the funds of the societies, and therefore the defendants will not suffer the least inconvenience for their acts. Whether that is an equitable result is not evident to people who are outside the unions.

THE case WALLER v. HOLLAND and HANNEN, which came before the Queen's Bench Division on Monday, presents difficulties which reveal a necessity for an amendment of the Metropolitan Building Acts. The intention of the Legislature was, to express it shortly, to interpose obstacles to the spread of fire by means of vertical divisions, which undoubtedly was a prudent arrangement; but there is no doubt that fires can be localised by means of fireproof horizontal divisions, and consequently in such cases the necessity for the upright divisions or party-walls is minimised. The Act practically assumes that the interior of every building is constructed of inflammable materials, and sufficient allowance is not made for fireproof floors by which a building becomes a series of superimposed, independent structures, each being secure. In the case in question the building consists of eight storeys, each being separated by floors, or rather horizontal divisions of concrete and iron. The aggregate content is 289,000 cubic feet, and as the limit in the Building Act is 216,000 cubic feet, it was claimed by the district surveyor that there should be party-walls introduced in order that the prescribed normal capacity might be respected. It does not appear to be maintained that the building is insecure and needs vertical divisions to insure the public safety. The magistrate could only be guided by the letter of the law, according to which all floors are sources of danger; and he made an order that the 216,000 feet limit must be recognised. The builders appealed. Their counsel, while suggesting that it would be necessary to expend 20,000*l.* in order to comply with a rule that in this particular case brought no advantage, wisely stood upon the technical objections that the building was not a warehouse or manufactory (for the floors above will be utilised as refreshment-rooms for assistants, kitchens, &c.), and as part was not rebuilt it could not be designated a new building. The case was sent back to the magistrate for a restatement on the latter point. We dare not anticipate the result, although it is almost evident; but we consider that cases of the kind should not have to depend on technicalities. Construction has advanced since the time of the early building acts, but Parliament has not sufficiently recognised a fact that is so manifest.

WE understand that a good many people are disappointed on seeing the small works by MEISSONIER which are shown in the Haymarket. It is not to be expected that everybody can understand the value of the studies which

form so large a part of the collection. Many of them are exceedingly careful, and denote the existence of power that was as prompt as exact. Why the artist should guard them so jealously from all eyes is not evident; it must have arisen either from a foolish desire to appear mysterious, or from a mixture of craft and insanity like that exhibited by TURNER. The French painter possessed so little inventive power or thought it was absurd to imagine that he could heighten the interest of his miniatures by concealing his processes. Nobody questioned his skill, and nobody could be persuaded to value him for anything more than execution. He was never able to put forth powers that would be equal to a noble subject. INGRES would have rejected him as a disciple as scornfully as DELACROIX. MEISSONIER was not deficient in self-knowledge, and he was not to be tempted into a display of weakness. He could not paint women and children, so he rarely introduced one of either into his works. He could not go beyond his models, and as they were not able to appear as in action for a sufficient space of time to suit MEISSONIER's needs, he preferred to paint figures in repose, for which he could utilise them. There was no largeness about his ideas or his handling; a study two feet high was beyond his grasp. Accordingly he concentrated his attention on little things. People were accustomed to associate miniatures with weakness, and they were so much surprised to see that scale was not a bar to the display of some of the qualities of the painter's art that they imagined MEISSONIER to be a sort of MICHEL ANGELO, and that it was more difficult to treat the infinitely little with success than the Sistine frescoes. The true value of MEISSONIER may be assessed if we bear in mind that during his long and most prosperous career he was without any influence on French painting. Some of the extravagances of artists might be taken as a protest against his style. In England his works are not likely to afford many lessons, but they are worth attention as evidence of the success which a very shrewd man gains when he makes commercial principles guide his art.

At the annual meeting of the Manchester Society of Architects, the president (Mr. SALOMONS) in the chair, the following gentlemen were elected as officers and members of the Council for session 1893 and 1894:—President, Mr. EDWARD SALOMONS; vice-presidents, Mr. JOHN HOLDEN and Mr. W. A. ROYLE; hon. sec., Mr. PAUL OGDEN; assist. hon. sec., Mr. EDWARD HEWITT; members of Council, Messrs. A. H. DAVIES-COLLEY, T. CHADWICK, JOHN ELY, R. KNILL FREEMAN, F. MEE, J. D. MOULD, JAMES MURGATROYD, J. H. WOODHOUSE, T. WORTHINGTON (Fellows) and Messrs. P. HESKETH, J. S. HODGSON and H. E. STELFOX (Associates); auditors, Messrs. HENRY BRIDGFORD, P. E. BARKER; education in architecture committee, Messrs. A. H. DAVIES-COLLEY, T. CHADWICK, JOHN ELY, F. MEE, J. D. MOULD, J. H. WOODHOUSE (Fellows), and Messrs. P. E. BARKER, P. HESKETH, E. P. HINDE, J. S. HODGSON, H. E. STELFOX and P. S. WORTHINGTON (Associates).

THE Antwerp International Exhibition will be inaugurated on May 5, 1894, and will remain open for a period of at least six months, closing at the latest on November 12. This exhibition will include industrial, scientific and artistic productions, as well as all kinds of commercial produce—embracing, in fact, the whole range of human activity. The articles to be exhibited have been divided into sixty-six groups, which are subdivided into classes and sections. During the exhibition and in connection therewith the Antwerp Royal Society of Fine Arts will hold an exhibition of painting, sculpture, engraving and architecture, to which artists of all countries can contribute. The exhibition buildings will be located in the new quarter of the city near the river Scheldt and the new maritime installations; they will cover an area of about 75 acres and will be connected with the railway. The general plan provides for the erection of more than 100,000 square yards of covered galleries. In the section of building industry will be comprised building materials, upholstery and decoration, tools and utensils belonging to the building trades, furniture, toys and basket-work, heating and ventilation, lighting, &c.

THE WATER-COLOUR SOCIETY'S EXHIBITION.

WHEN it is said that the summer exhibition of the Royal Society of Painters in Water-Colours is, if taken as a whole, of average merit, it will be evident that many most interesting drawings are to be seen. It should not be forgotten that the members, although they have the undivided use of a gallery, work under some restrictions. The majority of them gained reputation before they were admitted into the Society. Their styles were, so to speak, fixed by public estimation, and in consequence departures out of certain tracks would be risky. Purchasers of drawings have their own notions, and in a great many cases they insist on what they consider to be characteristic examples of the artists. Experiments may be tolerated elsewhere, but in the Pall Mall Gallery, where traditions are supposed to prevail, it is expected that drawings can be identified without the aid of a catalogue. It would be impolitic on the part of the members and associates if they were indifferent to the ideas or prejudices of their patrons, and hence it is that few surprises await a visitor in any of the Society's exhibitions.

The President has two drawings derived from the beginning of "Gil Blas"—*The First Adventure of Gil Blas* and *Gil Blas taken Prisoner by the Robbers*. Sir JOHN GILBERT has been identified with scenes from CERVANTES rather than from LE SAGE; but as his Spain and Spaniards are in a measure of an ideal kind they are adaptable to more than one writer. The figures are old acquaintances, and it is satisfactory to see they continue to be as vigorous as of yore. The Deputy-President also appeals to our memory. If we have not met the two hale and hearty folks who appear in *Good-morrow, Gaffer!* in the street of a village, they are as familiar to our mental experience as is the *Pretty Cockatoo*—a class of biped that is decorous, and could never be addicted to swearing or loose language. Some day we hope Mr. MARKS will have the courage to represent a bird that stands in need of a lesson from a missionary; his specimens are becoming rather monotonous in their over-respectability, and of late there is a tendency to dullness among them. Mr. HERKOMER's peasants are of rather an oppressive type, and the *Hagar*, who has acquired some of the airs of a tragedy-queen, does not excite pity, although a castaway mother and child by the roadside hardly need auxiliaries to become affecting. If compared with M. CAZIN's recent version of the subject we can discover how much can be gained by simple treatment. Theatrical experiments are not improving Mr. HERKOMER's manner of representing ordinary life. In the portraits of Mr. BRITON RIVIERE and Mr. J. W. NORTH there is no opportunity for dramatic display, and they are as excellent portraits in water-colours as Sir F. W. BURTON used to paint many years ago. Mr. BULLEID's *Doris* appears to be a portrait and shows a painstaking effort to gain relief. Another work of the portrait type is Mr. CUTHBERT RIGBY's *In Wonderland*—a boy meditating and excellently modelled. But the artist's admirers will probably be more satisfied with the drawings from the Kendal district, which are most interesting, and one, *Kendal Fair, Saturday Night*, was almost too difficult to attempt. Mr. LIONEL SMYTHE's *Boulogne-sur-Mer* is called "an impression," but the figures of fisher-girls and sailors show a less emphatic expression of defects than is suggested by that word. The drawing has an out-of-doors character, although every visitor to Boulogne will not recognise the scene as common. Mr. RADFORD's *Nox Æstiva* may appear somewhat statuesque, but there is no denying the care that has been taken to ensure graceful contours, and the difficulty of gaining success with a figure of the kind is unquestionable. Mr. RADFORD's *Reflection* also merits commendation. Mr. HENSHALL is ambitious to make water-colours subserve difficult problems in figure-painting. His *Mary Magdalene* may be modern in type, but it is suggestive of a grief that is genuine. *La Coquette*, by Mr. HENSHALL, on the other hand, is true comedy, and it is not every artist who has the power to pass from grave to gay with so much dexterity. There is enough visible in the gallery to suggest how earnest are the endeavours of the younger members to overcome the limitations which used to be fixed for their art. When designing *Charity Miss Con-*

STANCE PHILLOTT was no doubt thinking of some of the old masters, but we find a grace and tenderness about the figures which, we fear, could only be expressed by a woman's hand.

Mr. POYNTER's drawing *In the Roman Baths at Bath* would delight Major DAVIS, who has done so much to reveal Roman greatness, for the endeavour to express the quality of the old ashlar is a tribute to architecture. While admitting the value of what is done, we are not disposed to recommend the exercise as beneficial, for, judging by the results in Mr. POYNTER's case, it seems to us that the imitation of old masonry tends to stiffness and heaviness in handling when dealing with animated subjects. Partly architectural is the *Street Scene in Suez* by Mr. HENRY WALLIS. This is one of the best of the artist's later drawings, and glows with colour. His mannerism, in which vestiges of Preraphaelite hardness is apparent, hardly suits some subjects, but as we may suppose the general shop in Suez is under a fierce light, the precision of the detail seems to give truth to the scene. Eastern scenes in the gallery must always compel one to ask what has been done by Mr. CARL HAAG, who has made that class of work popular. His single drawing, *A Jerusalem Askenaz at Devotion*, is one of those characteristic figures which could only be produced by an artist whose acquaintance with the East was thorough and affectionate. Mr. R. W. ALLAN, who is fond of experiments in colour, and has not as yet made any province his own, has supplied some Eastern scenes which are more "blottesque" than is requisite. We prefer such northern scenes as *Crossing the Ford*, in which he expresses more than is possible to be done from brief visits to a place. Somewhat akin is Mr. A. MELVILLE, whose *Court of Lions* and *The Nile at Boulaek* have a claim to be taken as examples of Impressionism.

Mr. ALBERT GOODWIN is one of the few members whose experiments are tolerated. It may be that the public are more fascinated by his visionary scenes than by the views that are taken above the housetops of quiet English towns. This year he contributes an example of the former that was inspired by DANTE, and there are also views of Salisbury and Bridgnorth. Mr. THORNE WAITE wisely keeps to quiet country scenes under a subdued light, which have for so long found favour with the public; but in his *Evening Glow* he reveals a power that could be more often exerted with advantage. Mr. W. COLLINGWOOD was never more effective than this year in his mountain scenes, which are mainly Alpine subjects. Compared with so much majesty, the London views of Mr. MARSHALL, Mr. HODSON and Mr. GOODALL, with all their excellence, appear unpretending, and it is fortunate for all who represent buildings that most of the landscapists prefer lowland scenes. Mr. A. W. HUNT, in his *South Country Manor House*, takes care to allow only a glimpse of roofs, windows and chimneys to be seen amidst the trees; and Mr. BIRKET FOSTER, like Mrs. ALLINGHAM, embowers his cottage in vegetation. Mr. R. BEAVIS this year again displays his versatility. In a business sense it would be wiser if he kept himself to such scenes as *Crossing the Sands*, where his skill as a landscapist and animal painter can be combined in the production of a kind of drawing such as no other artist could produce so effectively.

BRIDGE CONSTRUCTION.*

ALTHOUGH books on construction are not sought after with eagerness in this country, yet in about five years the first edition of Professor CLAXTON FIDLER's work on bridge construction has been exhausted. So much success may be considered as somewhat exceptional, and arises from the combination of experience and simplicity of treatment which is displayed in every page. Engineering is not a subject which can be allowed to stand still for five years; there have been changes in bridge construction since the first appearance of the volume, but, as the author says, "these changes, however, do not appear to demand any considerable alteration in the methods of treatment that have been adopted in the work, nor in the numerical calculations

* *A Practical Treatise on Bridge Construction*. By T. Claxton Fidler, M.Inst.C.E., Professor of Engineering, University College, Dundee. Second edition. Charles Griffin & Co., Limited.

that it contains." But some extended applications of theory appear in the pages.

One relates to the important subject of the deflection of bridges under the passage of a train. The subject was investigated by a Royal Commission in the early days of iron bridge construction. In America bridges varying from 128 to 150 feet in span have been tested by Mr. A. S. ROBINSON for the Railway Commissioners of Ohio. The deflection was ascertained carefully for a rolling load. The "static deflection" under a load at rest was not observed; probably with stiff girders it would not be apparent, but it was assumed to be a mean between the two extremes of the rapid secondary vibrations which the girder generally exhibited. The effect of moving loads was as follows:—

It was found that during the passage of the engine the elastic vibrations had an extreme amplitude varying from '28 to '57 of the static deflection, so that the normal deflection was increased by a fraction varying from '14 to '285. When the bridge was being traversed by a long train of goods waggons, the elastic vibrations sometimes had an amplitude equal to the whole "static deflection," so that the normal deflection was increased by 50 per cent.; and notwithstanding the comparative lightness of the load per foot, the extreme deflection (including vibration) was sometimes as great as the highest value observed during the passage of the heavy engine. The great vibrations which were observed during the passage of the goods waggons is attributed to the coincidence between the spacing of the wheels and the spacing of the cross girders; and to the fact that with a certain speed of train, the reiterated incidence of the wheels upon the cross girders has a time-period coinciding with the natural period of vibration of the elastic bridge—so that the effect set up is comparable to the effect of the measured march of infantry, the impulses being due to the elastic spring of the intermediate stringers and perhaps also of the cross girders.

The American experiments are preferable to the English, for in the latter simple beams were subjected to tests, while the Americans took a bridge, which was a complicated piece of construction, and therefore liable to a variety of stresses, which all parts should be competent to sustain. In England it is common to assume a certain uniformity in the loading—say, one ton per foot run; but the Americans and the French prefer to assume concentrated loads on certain points, and to calculate the results of the strain of the arbitrary axle-loads on the various members of the bridge. Professor FIDLER shortly describes this arrangement when he says:—"In America it has for some time been the rule to calculate the required strength of railway bridges, taking as a standard load a certain type of engine and a certain type of car specified by the railway company or by the bridge building firm; while a similar plan has latterly been followed by the French Government, who have fixed the standard load as consisting of a train of goods' engines, weighing $15\frac{3}{4}$ tons each, and headed by two tender-engines, each engine weighing $55\frac{1}{2}$ tons, with a tender of $23\frac{5}{8}$ tons." Professor FIDLER explains how the test can be applied graphically by a comparatively simple process. The Board of Trade requirements do not err in laxity, and a good many French and American bridges would not be passed if the English standard were applied to them; but as civil engineers have to travel and work in many lands, it is an advantage to be familiar with the requirements of foreigners and competent to meet them.

Another subject that is allied to the foregoing is the provision to be made for wind pressure on railway bridges. In the majority of English bridges that was a factor which was not considered when the dimensions were worked out. Yet no casualties arose from the neglect. The Tay Bridge, which was the scene of the most melancholy of all accidents on iron structures, did not succumb to the Christmas storm, although if it were overturned by a breeze nobody who was acquainted with the structure would be amazed. A committee afterwards recommended that provision should be made for a pressure of 56 lbs. per square foot, as well as provision for the contingency of the overturning of the bridge, but the wisdom of the rules was not generally recognised. The Americans ostensibly are very careful in recognising the possibility of extraordinary storms operating with full force on a bridge, but the Professor is compelled to admit that "if we compare these pressures, taken over the area of a single girder only, with the actual section of the wind braces in many American bridges, we shall find that the resulting stress would be very high indeed, and would sometimes approach if it did not exceed the elastic limit."

The Americans undoubtedly excel us in the variety of

their girders. Long ago Mr. R. H. Bow devised a great number of ingenious arrangements of braced girders; but however much they were admired by pupils and assistants who kept up their knowledge of theory, they were not turned to much account in drawing-offices. The simplicity of which STEPHENSON and FAIRBAIRN approved still exerts an influence on English practice, although the great feat of spanning the Firth of Forth with cantilevers may cause a revolution in the way of dealing with simpler cases. Professor FIDLER contrasts the English and American ideas with accuracy in the following paragraph:—

In the foregoing survey and classification of bridge structures, it will be observed that we have completed a sort of circular tour, beginning and ending with the parallel girder. In the first instance the girder was considered as a simple structure or beam, carrying the whole uniform load by its resistance to transverse bending; but in the present chapter it has been regarded as a composite structure or truss. These two aspects represent the ideas which form the basis of English and American practice respectively. In England the simple beam was refined into a plate girder, and the plate web was improved by the substitution of diagonal bracing. But in America bridge construction was at first very largely carried out in timber or in combinations of timber and wrought-iron; and these materials were framed together in various forms of truss from which the wrought-iron trusses of the Linville, Whipple and other types have been developed. The forms of lattice-girder which have been reached by these two opposite lines of progress are identical in principle; but the same difference of fundamental ideas still marks the character of girder construction as carried out in the two countries. In American girders (or trusses as they are called) each member is treated as having a separate and simple function to perform; but in England, although the subdivision of function is allowed in theory, yet in practice all the members are riveted up together so as to make the girder as far as possible a rigid whole, resembling in some degree the solid beam from which it is derived.

All that we said in praise of the first edition of Professor CLAXTON FIDLER'S book when it appeared is confirmed by a perusal of the second edition. It is a model of a treatise on a constructional subject, theory being kept in subordination to practice. The author is not vain of his knowledge of mathematics, and he does not forget that his pages will be studied by men who read because they have to design. His book is therefore as useful to girder-makers as to students of bridge construction.

PETERBOROUGH CATHEDRAL.

A LECTURE was recently delivered in Peterborough by the Bishop. His lordship, according to the *Northampton Mercury*, said the subject of his address that evening was probably an exceedingly dull one. Not dull in itself, but only dull because they would find him a dull expositor on a subject which deserved a more adequate treatment than he could give it. He supposed they all had some pleasure in the place in which they lived, and he was bound to say for himself that he had rather an insatiable curiosity. He always wanted to find out as much as he could about anything he saw. Living under the cathedral at Peterborough he had seen a great deal of it, and he began to ask himself the question, "How did it come to be what it is?" One subject was just as good to learn about as another, and he never thought that one subject had more in it than another. Knowledge was very much like trade. A lady who was very anxious that her son should be successful in life asked one of the Rothschilds for advice as to what line her boy should take up. Rothschild said, "Selling matches in the streets. There is no better line than that, provided you sell plenty of them." It was the same with any branch of knowledge. Provided they knew plenty about it, it was always interesting. Nothing was interesting if they only knew a little about it. He would tell them as much about the cathedral of Peterborough as he had been able to find out, how it came to be what it is, and he might at least show them something of the activity of the England of the past, and of the qualities which had gone to make the England of the present, because the England of the present was after all but the product of the men who had laboured in the days of the past. It was always worth our while to remark that if we were to make the England of the present better, and hand it on in a better condition to those who were to come after us, it must be because we in our day and generation tried to imitate those qualities which our forefathers possessed, and the qualities to which we ought to be able to give greater effect because of the increased appliances which modern knowledge and science had put within our grasp. The dominant feature in the history of Peterborough was the fact that it was built on the verge of the Fen lands. The characteristic of this Fen land was not so much that it was covered with the sea water as that the drainage water from the main land ran down, and not being able to get in the sea, formed a

swamp. For nine months in the year it was a swamp, but in the summer it grew some coarse grass. The Fen contained numerous islands, upon which the towns were situated, the people maintaining themselves by fishing. In ancient times Peterborough was in the kingdom of Mercia, which was almost the last to receive Christianity. Penda, the king, was an irreclaimable heathen, but his son fell in love with the daughter of Oswin of Northumbria, and embraced the new faith, being baptized in 653. Penda was slain in a battle in 656, and Peada, his son, founded a monastery at Medeshampsted, the site of the present Peterborough. The work of the monks in those days consisted largely in colonising the surrounding districts, and the Fen country was a favourite spot for monastic institutions. The monasteries civilised the Fen district, and governed it in a sort of a way, but their work was destroyed in 870 by a Danish invasion. The Danes burnt the monastery of Medeshampsted, and slew the eighty-four monks. The Abbot of Crowland Abbey, founded by Guthlac, buried the bodies of the monks, and afterwards added a sepulchral monument, the stone of which was now preserved at Peterborough Cathedral. In 966 a monastic revival took place under Edgar and Dunstan. It was not entirely a sacerdotal revival. There had grown up a habit of reading into history a constant war of sacerdotalism against the civil forces of the country. This was quite unhistorical. The ecclesiastics were the only people of any education who were not engaged in fighting, and thus they were of necessity the officers of society for pacific purposes. Afterwards, as more of the laymen became educated and able to take up these duties, the ecclesiastics were gradually deprived of them, and he feared very much that they grumbled at the process. Dunstan's revival was for the better government of the outlying districts, and to reclaim the country from the Danes; and, as a matter of policy, he and Edgar worked for the restoration of the old monasteries. In 966 the second cathedral of Medeshampsted was built, and, for the purposes of protection, surrounded by a wall. The old name was lost, and the place was merely called Burgh. The monastery being dedicated to St. Peter, in later years it gained the name of Peterborough. Very little was known about that church. Hereward the Wake entered into an alliance with the Danes and invaded it in 1069, and burnt the monks' buildings and drove out the monks. The church was spared then, but in 1116 the whole of it was burnt. He was afraid this time that the disaster came upon it owing to an outburst of bad temper, and it was a very moral story. The story was that the Abbot de Seez, getting up one morning "in a bad way with himself," rated his cook because his breakfast was not prepared. The servant in the bakehouse, in his anger called out, "Come, devil, and blow the fire." The invitation was responded to, and the fire was blown to such purpose that the building was set on fire, and the flames spreading destroyed the church. It was decided to begin to rebuild, and he had to tell them the history of the way the church was rebuilt. The means of discovery were by such records as they possessed by monastic chronicles, and it was very strange how little they told them of the place in which they lived. A careful study of the architecture itself revealed to them, if they pursued it intelligently, the periods at which the building must have been stopped and the periods at which it was resumed, and they could make any building tell its own story. Northamptonshire owed its great name to its churches. They were famous all the world over, and they were famous for these two reasons. First of all, because of the splendid stone of Barnack, and secondly, because the water carriage could bring it everywhere where it was wanted. Builders of past time never built for population. The size of the congregation had not the least place in the architect's mind when he prepared the plan. That only occurred nowadays, when we had more people than we knew what to do with. The people in those days, too, stood and not sat in the churches. The very next year after the destruction of the building by fire John de Seez undertook the rebuilding, the choir being put up between 1117 and 1140. The question had arisen whether the present building contained any remains of the older one it succeeded. That had now been set at rest, because in the course of recent work at the cathedral the site of the old building had been discovered. The architectural magnificence of Peterborough Cathedral depended entirely on the existence of the great quarry of freestone at Barnack. From 1155 to 1175 Abbot William of Waterville built the transepts and the central tower. The last named consisted then of three storeys, if not four. From 1175 to 1184 Abbot Benedict built the nave. He originally intended to finish the nave at the third bay, but probably a visit to Lincoln Cathedral showed him the beauty of the western transept, and he added another bay, so that such a transept might be built at Peterborough without interfering with the monastic buildings. A further bay was built, and it became a burning question how to finish the cathedral. The changes of design which took place, and which were illustrated in the building, formed one of the most interesting processes in connection with any building he had examined. His lordship, by

means of a photograph of a couple of bays in the choir, showed and remarked on the quiet and dignified style of the original Norman architecture. The building of the cathedral extended over a period of years in which the architectural style of the country changed considerably; but the builders of Peterborough adhered to the old style till they reached the front, with the result that, as they got farther to the west, their style got more and more clumsy, because they were not working freely in accordance with the conceptions of the time. Time proved that the pillars of the centre tower were not strong enough to bear the tower's weight, a defect almost always found in Early English architecture. Had the builders gone down another 18 inches they would have reached the rock, but they had reasons of their own for placing the foundations upon the earth. The result was that the tower had to be lowered, and was now a squat structure not in proportion with the length of the cathedral. A most interesting and lucid account of the history of the west front was next given by his lordship, who remarked that when that was reached the builders did not feel there was any need to restrict themselves to the Norman style, but allowed themselves to proceed with their work in Early English. The west front became the chief object, and the original design was modified considerably from time to time. The front presented really a great stone verandah connecting the two flanking towers. They were told that the west front of Peterborough Cathedral was the most magnificent piece of architecture in England, but he was bound to say that he did not think so. When they saw a front consisting of three huge arches, they naturally asked what those arches were meant to contain. The design appeared to have been for them to have contained three miserable little doorways, for the early English architects were sadly deficient in the matter of doorways and doors. To have arches which ought to be doors, and to have such doors underneath them, was not a thing to be mentioned as the noble achievement of a sane and sober architect. Pointing out upon the photograph the incongruities which resulted from the frequent change of design, his lordship especially dwelt upon the lovely work of the pediments at the top of the archways. Sometimes they talked as if everyone who lived in the present day was stupid, and as if everything that was done in the old days was wise, but they saw that people in the old days, though they might make beautiful things, yet occasionally did not exhibit beauty and wisdom hand in hand. In many old buildings they saw clearly that the architect began in an exceedingly rash way, and allowed the design to grow as it would under his own hands. Very often he did not know when he began or where he was going to finish, and that was the case with the architect of the Peterborough Cathedral. There was, curiously, no record of the building of the west front, but it must have been between the years 1200 and 1230. The cathedral was consecrated in 1237, and in 1260 Richard, of London, gave a peal of bells called "Les Londres." It was then found that there was nowhere to put them. A tower was therefore built on one side of the cathedral, and then it was discovered that this lent a somewhat lop-sided appearance to the structure. The old builders were not such slaves to uniformity as modern people, so that to balance the bell tower, instead of erecting a second tower on the other side, they added a lovely spire to the flanking tower most remote from the bell tower by way of a counterpoise. Then the second flanking tower was felt to need a similar treatment, and a spire was added to that, though quite dissimilar to the first. Having explained the reason for the span of the two side arches being greater than the middle span, his lordship spoke of the small porch which was added in 1370. It entirely ruined the appearance of the three archways, but its object was to act as buttress to the two centre pillars which were found to be leaning. Of itself the porch was a beautiful bit of work in the Perpendicular style. His lordship next referred to the subsequent alterations, especially mentioning the reconstruction of the windows from the old Norman style to allow for the introduction of more glass. The rich tracery of this later work was illustrated, and the history of the eastern chapel, added round the old apse, and its stained windows, was given. The different styles of the doorways were also shown, in addition to several views of different parts of the interior of the cathedral. His lordship, in concluding, said he loved architecture above all other arts, and he thought the great reason why he loved it was because it was of all other arts the most popular art, it was absolutely the most democratic art, and it appealed to everyone, it could be seen by everyone, and it was the possession of everybody alike. Architecture they could see in the streets as they passed by, and they should try to learn to love it and see in it the beautiful things that came from the minds of those of former times, the conceptions they left behind them, which told them of their aspirations, their endeavours and their longings. Look at St. Peter's Church, Northampton. If they passed such a building as that, and caught the beauty of its mouldings and the delicacy of its tracery they might feel as though there came a voice to them from the past that told them to be of good

cheer, a voice that told them they were the inheritors of traditions, and a voice that bid them also to see that in their hands those traditions suffered nothing, but were handed on to those who came after them enhanced in value.

THE BATEMAN HEIRLOOMS.

THE important collection of works of art and antiquities known as the Bateman heirlooms have been sold. The most important lots were as follows:—Enamels.—A chalice-shaped cup of Venetian enamel of the sixteenth century, 61*l*. (Money); an important triptych of Limoges enamel representing the Adoration with St. Michael and St. Catherine in the two wings, 156*l*. (Rollin); an alto-relievo in Oriental alabaster of German work, circa 1550, from Lord Shrewsbury's collection, 122*l*. Ivories.—An important ivory diptych of the sixth and seventh century, described by the late Mr. Bateman "as matchless in this as specimens of the period," 182*l*.; an ivory carving of Italian work of the fourteenth, representing the Coronation of the Blessed Virgin, in fine condition, 70*l*.; leaf of a diptych of the fourteenth century, representing the Coronation of the B.V. and the Nativity, 70*l*.; a valuable diptych, or probably covers of the Gospels, formed of two large plaques of ivory, in three compartments, representing incidents of the life of the Saviour, the whole within an acanthus leaf border. This fine example of early Christian art, originally from the cathedral of Trèves, formed a portion of the collection of Samuel Rogers. The ivory carvings are assigned to the eighth and the metal to the thirteenth century. There was much competition for this, and eventually it was secured for 1,000*l*. It sold for something less than 400*l*. in the Roger's sale. Metal work.—The head of a pastoral staff, twelfth century, in bronze gilt, of simple volute form, 50*l*.; a gorget of the seventeenth century, in copper, richly gilt, of bold repoussé work, elaborately chased, with a battle scene, from Lord Shrewsbury's collection, 63*l*.; a bronze ewer of German work, 52*l*.; a curious equestrian bronze figure of a knight, thirteenth century, 61*l*.; a fine silver mace, given by Charles I. to the Corporation of Leicester, 58*l*. (Usher); a horn book of the seventeenth century, with portrait of Charles I. on reverse, 65*l*. The heirlooms realised 3,133*l*.

EDINBURGH ARCHITECTURAL ASSOCIATION.

AT the meeting of this Association in the Royal Institution, Mr. W. W. Robertson, H.M. Board of Works, president, in the chair, Mr. A. H. Millar, F.S.A. Scot., read a paper on "The Old Howff of Dundee," on many of the monuments and their inscriptions in which burying-ground he commented and illustrated by means of the limelight. He traced the origin of the cemetery, pointing out that the orchard of the Franciscan monastery had been granted by Queen Mary for that purpose in 1567, and that for three hundred years afterwards the "Howff" (which had been so named from the fact that up to 1778 it was used by the crafts as their meeting-place) continued to be the chief place of interment in the town. Consequently the sacred spot was peculiarly rich in memorial-stones, indicating the alterations that had from time to time taken place in the artistic tastes of the community, and Mr. Millar gave it as his opinion that no other Scottish burial-place contained so many sculptured memorial bearings of extinct Scottish families. At the close of the lecture—in connection with which about one hundred lantern slides were used—the President of the Association and the Lyon King of Arms (Mr. Balfour Paul) and others testified to the excellence of what had been brought before the Society, the last-named gentleman alluding to the interest which attached to many of the ancient gravestones of the "Howff," particularly from a heraldic point of view. Subsequently Mr. Millar received the cordial thanks of the Association.

FORESTRY IN AMERICA.

THE *Engineering News*, New York, says:—The importance of the systematic tests and investigations of the timber and timber supplies of the United States, which have been instituted and commenced by the Forestry Division of the United States Department of Agriculture, has been pointed out several times in the columns of this paper. It has been shown that this is a work which deserves the aid of the Government, being in the public interest; but we learn that although many leading railway engineers, architects, professors of engineering and others interested in the timber tests have written letters expressing this view to their representatives and senators and to the committee on manufacturing, in whose hands the special appropriation for the work was pigeon-holed, neither the committee nor the House paid any attention to this expression of public interest. The Senate, however, realised that there was value in the work and sincerity in its endorers, and increased the appropriations for the Forestry Division by 8,000 dols., and

that is 20 per cent. of the amount asked and considered,* by those in charge as necessary to continue the work on a proper business basis. Under these circumstances the testing will be discontinued until after July, when the new appropriations will become available, and then proceed at the slow pace which Congress has set. While the result of the efforts of those who took active interest in securing appropriations for the work were not crowned with that success which they deserved, this is the only proper method of influencing legislation, and those interested in the investigation should not fail to move again when the new Congress assembles.

The first compilation of test results is now in the hands of the printer, and will probably be issued in a few weeks as Bulletin No. 3, Timber Physics, Part II. It will contain the results obtained on longleaf pine, and will especially discuss in detail the results of tests and examinations of bled and unbled timber, results which in themselves justify the expenditure by the Government of money on such work. Part I. was issued several months ago. At the World's Columbian Exposition the Forestry Division will exhibit the methods pursued in this work, which will be of interest, since nowhere in the world has such comprehensive and systematic investigation of timbers been ever devised. The working plans for a similar undertaking by the Prussian Government have only just been perfected. Another exhibit of interest to railway engineers and those interested in reducing forest waste will be a collection of the most approved types of metal railway ties used throughout the world, and a complete set of coloured drawings illustrating the various forms of metal ties now in use, being copies of the original drawings from which the plates were made for the report on "The Use of Metal Railway Ties," made to the United States Government by Mr. E. E. Russell Tratman in 1890. This report showed that, excluding the United States and Canada, which have no extent of metal track, over 13 per cent. of the railway mileage of the world is laid with metal track. The exhibit will also include metal tie-plates, which are an important addition to railway track equipment.

TESSERÆ.

Mosaic Floors.

MOSAIC floors have been in use from a very early period. The most ancient on record is the floor in the palace of King Ahasuerus at Shushan, described in the 1st chapter of the Book of Esther as "a pavement of red, and blue, and white, and black marble." These were the prevailing colours also in the Greek and Roman pavements. They were generally formed of small cubes, some of them very minute, arranged in various interlaced and flowing patterns, principally geometrical, with animals and other figures interspersed. Pliny says, "The most celebrated Greek mosaic worker was Sosus, who strewed at Pergamus what they call 'the unswept room' (*Asaroton Aicon*), because he had represented all the leavings of a repast in various colours on the floor." The numerous Roman pavements discovered in different parts of this country are composed of tesserae not exceeding an inch cube, and the principal colours were red, black and white. Ormerod, in describing the Roman bath discovered in Watergate Street, Chester, in January 1779, mentions "an adjoining large chamber with a tessellated pavement of black, white and red tiles, about an inch square." Sir Robert Atkyns, in his work on the present state of Gloucestershire, p. 350, says:—"There was accidentally discovered, in a meadow near the town of Cirencester, an ancient building underground. It was 50 feet long, 40 feet broad, and 4 feet high, supported by 100 brick pillars, inlaid very curiously with tesseraic work, with stones of divers colours, little bigger than dice." The fragments of Roman bricks which are so frequently found in Chester are also commonly called tiles, but they are quite distinct from floor tiles, being usually about a foot and a half long, a foot wide, and one and a half inch thick, of unglazed red clay. These were formerly called wall tiles, and from this term they received the name Roman tiles, but they were principally used as bricks in constructing walls, and some of them as roofing and water tiles. Earthenware of this description, because they were called tiles, seem to have conveyed an idea to some minds that all tiles discovered below the ground are Roman. Tiles were, however, much used for floors in the Middle Ages also; but these are easily distinguished from the Roman pavements, as the tesserae of the latter scarcely ever exceeded an inch cube, whereas the Middle Age tiles vary from 4 to 6 inches square; moreover, the Roman tesserae were each of a self colour, the pattern being formed by combining a number of them so as to compose a picture, just as the coloured stitches in woolwork are arranged in the present day, whereas the pattern on a Mediæval floor is inlaid in the tile itself. Ornamental tiles of this kind were much used for paving the floors of churches and religious houses, so that, being generally confined to buildings of a sacred character, wherever they are found, there is good reason to suppose that a religious edifice had at one time occupied the

site. There are few samples, however, of an earlier date than about the middle of the thirteenth century. The earliest are of red clay, stamped with a pattern, and the sinking filled up with white clay, and glazed. Such tiles are frequently ornamented with foliage in various colours and forms, according to the different periods in which they were made.

English Patronage of Painting.

We have private patronage in England to an extent which no other nation possesses. Let us encourage this market by supplying it with excellence rather than choking it with abundance: husband it in every way; let not its importance be underrated. To this class of patrons we owe the chief works of art in our land. The whole range of landscape-painting, scenes of familiar life, all our portraiture and a great proportion of our historical works are the offspring of individual encouragement. The palaces of Rome, of Florence, of Bologna and of Venice were filled with works from the like source. It was by this, and this alone, that the great families of the Doria, the Colonna and the Altieri acquired their magnificent specimens of Claude Lorraine and of the Poussins: it was by this that the Farnese, the Farnesina, the Rospigliosi and the Ludovisi were decorated; by this the family of Orleans became possessed of the Sacraments of Poussin; and by this has the Burgomaster Six been handed down to our day as the friend and benefactor of Rembrandt. All who desire to distinguish themselves and grow into eminence in art; all who begin to plume, as it were, their wings for an untried flight in the higher or the humbler regions of art, must hope for success through patronage such as this—a patronage which surpasses far that of many foreign governments, and has been established here both by patriotism and generosity. To this source all that the genius of our school has produced must stand indebted for origin and support. This is a feature in our art, as well as a proof of the increasing taste and growing wealth of the empire. Activity of mind in the artist, a variety and diversity of subject, an originality of style, splendour in colour, a happy adaptation of the theme to the feeling of every variety of being: an observance of these ruling points has enabled English art to penetrate and become an object of demand in every country in the world.

The "Erber," Thames Street.

On the south side of Thames Street, between the Steel Yard and Dowgate, stood that magnificent mansion of the olden time, the "Erber," so intimately associated with the stirring times of chivalry, and with more than one illustrious name. It was granted by Edward III. to the gallant and learned Sir Geoffrey Le Scrope. Its next illustrious occupant was John Lord Neville of Raby, the heroic companion in arms of Edward III., from whom it descended to his son, Ralph Neville, first Earl of Westmoreland. This was that powerful lord who was so instrumental in raising Henry Duke of Lancaster to the throne as Henry IV., and who afterwards so distinguished himself in that Border warfare and in those successful operations against the Percys which led to the battle of Shrewsbury and to the untimely end of the impetuous and heroic Harry Hotspur. From the Earl of Westmoreland the "Erber" passed into the possession of another branch of the Nevilles, the Earls of Salisbury and Warwick. But the principal interest which attaches itself to the spot is from its having been the residence of the great "King-maker," Richard, Earl of Warwick. Some idea may be formed of his princely hospitality from the fact that at his house in London no fewer than six oxen were daily consumed by his retainers at breakfast, any person, moreover, who happened to have access to his establishment being permitted to take away with him "as much sodden and roast meat as he might carry upon a long dagger." After the death of the Earl the ragged staff and white cross disappeared from over the portals of the "Erber," and not long afterwards we find it occupied by the ill-fated George Duke of Clarence, "false, fleeting, perjured Clarence," who obtained a grant of it from Parliament in right of his wife, Isabel, daughter of the "King-maker." After the death of Clarence the "Erber" became the residence of his younger brother, Richard Duke of Gloucester, on whose usurpation as Richard III. we find it styled the King's Palace, and undergoing considerable repairs. During the brief reign of Richard it was occupied for him by one Ralph Darnel, a yeoman of the crown, but on the death of the usurper was restored to Edward, son of the Duke of Clarence, in whose possession it remained till his attainder in August 1500. It was rebuilt in 1584 by Sir Thomas Pullison, Lord Mayor of London, and not long afterwards became, according to Stow, the residence of the great navigator and hero Sir Francis Drake.

The Engraving of "The Death of Lord Chatham."

"The Death of Lord Chatham," by Bartolozzi, is too well known to need description. Although a work of great ability and immense labour, it has never become a standard, or at all a popular print. It was many years in hand, and the price agreed upon with Copley (2,000 guineas) was nearly expended

by Bartolozzi on assistance, which proved for the most part, according to his account, worse than none. Testolini, a fellow-countryman, was employed on it for three or four years, and to his entire satisfaction, as expressed by his principal during its progress; but their engagement terminated in a quarrel, and Bartolozzi erased much of what Testolini had done. Delattre, the ordinary and regular assistant of Bartolozzi, also contributed his aid, and was afterwards commissioned by Copley to make a smaller engraving, a copy of the larger, for which he engaged to pay him five or six hundred guineas, but afterwards refused to receive the plate on the plea of gross imperfection in its execution. This led ultimately (1801) to a lawsuit, which excited great interest in the little world of art, and ended in favour of Delattre, to whom the jury gave a verdict for the whole amount of his claim. The plate, however, though paid for, was never published. The motive which influenced Copley in having a smaller engraving made was with the view of preventing surreptitious copies being circulated to the detriment of the larger one, from the successful sale of which he expected extraordinary results, in which he must have been greatly disappointed.

Chantrey and the Nelson Column.

Chantrey was always consulted by the heads of the government on the propriety of public testimonials. Among others he was desired to send his opinion as to the propriety of erecting a column, with a statue on the top, to the memory of Lord Nelson. He seriously and reasonably objected to a column, for a column ought to be part of a building, or if it be used as a monument, it should be treated as a biographical volume, with the acts of the hero sculptured on the shaft of the pillar on the capital of which he stands, similar to those of Trajan and Antoninus. Chantrey also wished to see the useful united with the commemorative, and would have preferred an architectural edifice, adapted to accommodate (with dwellings rent-free) the veteran officers of the navy, and the site adorned by a fine statue of Nelson, forming altogether a memorial worthy of the hero and indicative of the gratitude, generosity and benevolence of the nation.

Roman Glass.

Thick sheets of glass of various colours appear to have been laid down for paving floors, and to have been attached as a lining to the walls and ceilings of apartments in dwelling-houses, just as scagliola is frequently employed in Italy and occasionally in our own country also. Rooms fitted up in this way were called *vitrea camera*, and the panels *vitrea quadratura*. Such was the kind of decoration introduced by Scaurus for the scene of his theatre, not columns nor pillars of glass as some, nor bas-reliefs as others, have imagined. The question whether glass windows were known to the ancients has, after much discussion, been set at rest by the excavations at Pompeii, for not only have many fragments of flat glass been disinterred from time to time, but in the tepidarium of the public baths a bronze lattice came to light with some of the panes still inserted in the frame, so as to determine at once not only their existence but the mode in which they were secured and arranged. From the time that pure glass became known, it must have been remarked that when darkened upon one side, it possessed the property of reflecting images. We are certain that an attempt was made by the Sidonians to make looking-glasses, and equally certain that it must have failed, for the use of metallic mirrors, which are more costly in the first instance, which require constant care and attain but imperfectly the end desired, was universal under the empire. A strange story with regard to an alleged invention of malleable glass is found in Petronius, is told still more circumstantially by Dion Cassius, and is alluded to by Pliny, with an expression of doubt, however, as to its truth. An artist appeared before Tiberius with a cup of glass. This he dashed violently upon the ground. When taken up it was neither broken nor cracked, but dented like a piece of metal. The man then produced a mallet and hammered it back into its original shape. The emperor inquired whether anyone was acquainted with the secret, and was answered in the negative, upon which the order was given that he should instantly be beheaded lest the precious metals might lose their value should such a composition become generally known.

The Process of Etching.

Etching, as a process for the ornamentation of metal surfaces, was practised as early as the middle of the fourteenth century. As to who first employed it for the purpose of taking impressions authorities are in doubt, but to Albrecht Dürer, of Nürnberg, we owe the first important works, not commensurate, however, in success with the results obtained by him with the graver. Of his pieces, of which he etched some nine, the *Virgin and Child* and a *St. Jerome*, dated 1512, are considered the most satisfactory. The practice may be described shortly as follows:—A cleaned plate of polished copper is covered with a varnish protecting layer called "etching ground." To this the design is either transferred or drawn at once, or worked

out on the ground with the aid of the etching-point or needle. This point—a stout piece of steel wire, varying in thickness inserted in a handle—removes the ground from the metal plate wherever it works or passes, thus exposing the plate to the action of an acid when poured over it, as it actually is in the next stage of the process. A low wall of wax having been built up along the margin of the plate, dilute nitrous acid is poured over the latter. This stage is called “biting in.” The acid coming into immediate contact with the copper, where the etching-needle has scraped away the ground as it traced out the design, eats away or corrodes out the metal more or less deeply the stronger the acid and the longer time it is allowed to remain. Where the ground has not been removed by the needle the acid cannot act upon the plate. Thus, where it has been taken away the design remains bitten into the copper, and visible as soon as the remains of the acid and etching-ground are cleared off. The plate is then inked, and an impression or proof obtained as from other engraved objects. In addition to the action of the acid, the dry point—so termed from no acid following its use—is brought into requisition, producing more or less of what is known as “burr.” This burr, during the process of printing, gives off rich velvety gradations to the impression. The burr is, in fact, the ridge of the copper material thrown up by the dry point on the left edge of the furrow, as the instrument cuts its way through the metal, which, catching and retaining the ink in a peculiar manner, protects a certain margin of smooth copper against the operation of the printer’s hands when wiping the plate. The ink remains on this smooth copper, but passes away from the burr with a delicate gradation, giving a peculiar softness to the line.

Polychromy of Greek Temples.

The discovery of Greek temples coloured on the exterior is doubtless a very remarkable fact in archæology, for if these monuments appeared to many persons to reject the application of colours in their external decoration they were assuredly made by the Greeks. Now, it is impossible not to admit that it was among these people that the alliance of colours with architecture was made, not at the epoch of its decline, but at a period when they erected monuments in the best style; in fact, the ruins of coloured temples discovered by the excavations made in Greece, Italy and Sicily, in places where many Greek colonies prospered, have this characteristic in an unmistakable degree. If we seek the cause which has determined the Greek architect to seize upon one of the most powerful means that the painter has of addressing the eye, we shall find it especially in a taste for colours rather than in the intention of rendering the various parts of an edifice more distinct from each other by colouring them differently and of substituting painted ornaments for ornaments in relief, whether sculptured or moulded, or of augmenting the relief these ornaments already possessed; finally, the communication of the Greeks with the Egyptians may have induced them to imitate the latter in this application of colours to monuments. In the coloured drawings of Greek monuments we may remark not only the number of colours employed in these monuments—white, black, red, yellow, green and blue—but also the use which has been made of them under the relation of variety and purity of tint, of distinct view of the parts, and of the harmony of the whole. In the work of the Duke de Serra di Falco upon the “Antiquities of Selinonte,” we see coloured designs representing the ruins of Greek temples, where the principal lines, such as the fillets of the architrave and those of the cornice are red, the mutules blue and their guttæ white; the triglyphs blue, their channels black and their guttæ white, and the more extended parts of the frieze and the cornice as well as the architrave are of light yellow. We see that red, a brilliant colour, designated the greater part of the principal lines; that blue associated with black in the triglyphs and their channels formed an harmonious ensemble distinct from the neighbouring parts; also that the dominant colour, light yellow, produced a much better effect to what it would if the most intense or the most sombre colours had predominated. Finally, the colours were distributed in the most intelligent manner possible without being motley, presenting a variety and lightness in the tints with easy separation of parts.

Greek Painting.

Upon the authority of Quintilian painting was considered by the Romans to have flourished chiefly in the age of Alexander and his immediate successors. In the mere mastery of the technical difficulties of the art it doubtless did; but the great period of Grecian art was from Cimon and Pericles to the time of Alexander. Polygnotus of Thasos, who settled in Athens about 460 B.C., established painting in all the essential principles of the art. Character, form, and all that is essential in colouring were thoroughly attained by Polygnotus and his contemporaries. In the succeeding generation the art was rendered dramatic by Apollodorus, Zeuxis, Parrhasius, Timanthes, Eupompus and their contemporaries. The imitation of the local and accidental appearances of objects was added to the generic or essential style of Polygnotus; character

and form were enhanced by the addition of local colour and tone and dramatic fidelity of composition. The Alexandrian period, which was one only of refinement, did but add variety of method and effect to the already perfect art of the preceding age. The great masters of this period were Pamphilus, Apelles, Protogenes, Euphranor, Nicias Nicomachus, Aristides, Pausias, and others—in essentials probably all more or less equal, yet each striving after distinction by undue attention to one or more of the mere technical qualities of art. Thus we find one distinguished for grace, another for high finish, a third for facility, others for peculiar effects of light and shade or bold foreshortening, some for ingenious or novel devices others, again, for skilful grouping, and one only, Aristides of Thebes, for expression. As these mere technical excellences of art were made thus prominent the higher qualities of art were overlooked by the succeeding generation of artists, and the form became paramount over the essence, even with the very pupils of these great painters. This caused the rapid decline of Grecian art which immediately supervened on the close of the Alexandrian age. A glance at the similar revolution of taste and practice which took place in Italian art in the beginning of the seventeenth century will render this change intelligible. The school of the Carracci, though a partial revival at the time, was, when compared with the Roman and Florentine schools at the commencement of the sixteenth century, just such a transition from essence to form, from sentiment to sense, as that which it has been endeavoured to show took place in Grecian art immediately after the period of Alexander. It should be borne in mind that the paintings of Pompeii are the ordinary chamber decorations of an insignificant provincial town, and that they were executed at an age when, according to Roman writers, the art was in a disgraceful state. If we compare the Pompeian remains with our own provincial, or even metropolitan chamber decorations from the establishment of the arts down to the present day, we shall find the comparison greatly in favour of the ancients. There have been, however, many noble specimens of the art discovered at Pompeii and Herculaneum, both as regards facility of execution and composition. The great mosaic *Battle of Alexander*, discovered in 1831, is, even as a composition, worthy of any age of art, and has much merit of execution, even as a mosaic, though, from its great superiority as a work of art, it is evidently the copy of some celebrated picture of some former period; it abounds in skilful foreshortenings, and is, on the whole, a noble battlepiece. In the mere mural decorations also of Pompeii there are many successful attempts at perspective. It is well known that the Greeks were acquainted with perspective, for perspective scenery (scenography) was introduced on the Greek stage as early as the time of Æschylus, though, perhaps, not generally until the time of Sophocles.

The Epic Spirit in Sculpture.

The whole scenery of a picture may, of course, be regarded as *dramatis personæ*, as much so as the painted actors of the canvas or the living actors of the stage. That rock is a stony-hearted villain: that flower is your sister asleep: the brook is a beautiful idiot, babbling nonsense. But apart from such generalities, be it observed that painting is romantic and that sculpture is classical drama, which expression may be taken as meaning, in the one case, a drama truly such, in the other, a drama conceived in an epic spirit. A. W. Schlegel reports the saying of Hemsterhuys, that the ancient painters were too much of sculptors, and that the modern sculptors are too much of painters. According to the above interpretation the remark means that the ancient pictures were epic in their tone and that modern sculptures are more truly dramatic; that the ancient artists could not save themselves, but whether with the pencil or the chisel would give a Classical or epic meaning to their works. For, as a general rule, in sculpture (that is to say Greek sculpture) the face is without expression, at least of present feeling, whereas in Christian art it is all in all. Wherever character can be traced in the countenances of Greek sculpture it is almost always an unmoved character, a character without present energy, but hinting a thousand probabilities of past history, a thousand possibilities of the future, past and future—the symbols of those epic and lyrical tendencies which go to form the classical drama. The epic tone of sculpture is also shown by the fact that often a character has no individual expression whatsoever, and is recognised only by some conventional mark attached. “Take from Apollo his lyre,” says Sir Joshua Reynolds, “from Bacchus his thyrsus and vine-leaves, and from Meleager the boar’s head, and there will remain little or no difference in their characters. In a Juno, Minerva or Flora the idea of the artist seems to have gone no further than representing perfect beauty, and afterwards adding the proper attributes with a total indifference to which he gave them.” Instead of making the statue speak for itself, as all purely dramatic art is bound to do, there is added to tell the tale an attribute, as Sir Joshua calls it—an arbitrary sign, a shorthand narrative.

NOTES AND COMMENTS.

OBJECTIONS to the sale of the Hunter collection of coins have been formally lodged by the Senate of Glasgow University with the Universities' Commission. Dr. HUNTER'S will, it appears, contains instructions that the collections were to be delivered to the principal and faculty of the Collège of Glasgow, "to be kept and preserved by them and their successors for ever, to and for the use of the said principal and faculty of the Collège of Glasgow." Whatever effect the Universities (Scotland) Acts of 1858 and 1889 may have had in transferring from one body to another the management of property belonging to the university or of property held by the university in trust, there was no authority given for converting any property held in trust into an asset of the university. Of existing university bodies, the Senate is the one among whose members the successors of the principal and faculty are to be found, and consequently they take a special interest in anything that may affect the Hunterian collection. The Senate therefore, in the first place, object to the sale of the Hunterian collection of coins or of any part thereof, because the testator directed that the collection was to be kept and preserved for ever for the use of the university. Secondly, the Senate object to the proposal because it commits a power of sale to the university court that contains only one permanent member. The Senate object, in the third place, to apply the proceeds of the sale to purposes outside those contemplated by the testator, viz. to the maintenance or extension "of other libraries and museums" belonging to the university. Finally, the Senate object because the proposal which it contains is highly inexpedient and inopportune. It is inopportune because it proposes to alienate from the university a collection which would be most effective for the teaching and illustration of history at the very time when the commissioners are proposing to establish a Chair of History—a time, too, when universities elsewhere are using their best efforts to procure similar collections. At the date when it came into the custody of the university the Hunterian collection of coins was the most important and valuable in the United Kingdom, and even at the present time the only collection in this country which excels it is that in the British Museum. No other treasure in its keeping has contributed so much to the fame of Glasgow University; and, besides the uses which the collection subserves to members of the university and others in Scotland, numerous communications and inquiries involving references to its contents are received from universities and other learned bodies, as well as from persons interested in art and archæology in foreign parts. It is inexpedient to authorise the sale of this collection—a collection which could never by any possibility be replaced—for such sale would greatly injure the reputation of the university at home and abroad, would cripple its resources for teaching and illustration, and would take away all hope of similar benefactions being made to it in future.

THE site for the proposed City Hall in New York has been selected, but it is not generally approved. The façade will be on a line with the existing hall, which is to be removed, but the Court House, which is associated with many scandals, is to be preserved. The design for the new building will be obtained by competition. Drawings are to be submitted not later than September 1. Six designs will be selected by three architects to be nominated by the Board of Commissioners. One out of the six will be chosen by the Board, and the architect, if of adequate standing, will be appointed architect for the building. His commission will be 5 per cent. on the first million of dollars expended, 4 per cent. on the second million, and 3 per cent. on the remaining outlay. The authors of each of the five designs which remain will receive 2,000 dols. The new hall is to provide accommodation for present needs amounting to 270,000 square feet, and it is calculated that from 50,000 to 100,000 square feet will be required in the future in addition. It is desirable that each storey should have at least 70,000 square feet, in order that it may not be necessary to have any considerable part of the building of a greater height than five storeys. The building is to be throughout of fireproof construction, and especial care is to

be taken in imparting security to the offices in which public records are kept. The sum named for outlay is 4,000,000 dols., which is insufficient. The drawings are to be on a scale of 16 feet to the inch, except the block plan, which is to be 64 feet to the inch. Shadows or shading will not be allowed, and the perspective is to be without accessories. A single figure is allowed to indicate scale. The drawings are to be without any mark, to be on paper measuring 29 inches by 44 inches, and to be sent flat in a portfolio.

WHITEWASH is not always an evil thing. In the eighteenth century it was the means of preserving some remarkable examples of French sculpture. The great CONDÉ, who always sought after grandeur in whatever was undertaken by him, erected a monument to his father, which exemplified the height attained by sculpture in the age of LOUIS QUATORZE. When, at the close of the eighteenth century, the Revolutionists were struggling against Europe, there was a demand for cannon, and many a work of art was sacrificed to obtain materials for casting them. The Condé monument was doomed. Some sympathising friend of the family covered the statue with a thick coating of whitewash, and the Committee of Artillery, being probably in a hurry, came to the conclusion that the figures were only made of plaster, and rejected them. They were then lodged in one of the musées until 1816, when they were returned to the family. The Duc d'AUMALE, when they came into his possession, with the aid of M. DAUMET, set them up in the chapel of the Château of Chantilly, where they guard the cenotaph in which the heart of the great CONDÉ is mouldering. It is to be hoped that the statues will never be again reclaimed as war material, for the thickest whitewash could no longer deceive inquisitors.

THE syllabus of the lectures on architecture, building construction and modern practice, by Professor BANISTER FLETCHER, which will be delivered at King's College, deserves the attention of students of architecture and building. Care has been taken to give unity to the course. It is also a great advantage for students to possess a museum of casts, models, photographs and drawings which illustrate the history of architecture as well as the progress of construction. The Carpenters' Company have most loyally aided Professor BANISTER FLETCHER in securing the best appliances for the instruction of the students.

For some time past there has been agitation in Cardiff respecting a new town hall, and some of the local architects have taken time by the forelock, since they have endeavoured to gain the approval of the inhabitants for their plans. The Marquis of BUTE should have much to say on such a project, for he is not only a most generous and self-sacrificing landlord, but he has expended more money on architecture than any of his contemporaries. When therefore it is said that while his lordship is anxious to assist the Corporation in providing such additional or improved accommodation as may be necessary, still, after giving the whole matter most serious consideration, his lordship has arrived at the conclusion that there is no necessity for the removal of the town hall from the present site, the people of Cardiff would do well to reflect on the suggestion. The Marquis considers that Cardiff has at present an adequate site, but he is willing, if the Cardiff Corporation so desire, to sell them for the purpose of erecting police courts a portion of the lower end of the Cardiff Arms Park. Lord BUTE desires to facilitate the carrying out of improvements or extensions, but he hopes, in the interests of the ratepayers, that no expenditure will be incurred beyond that necessary for providing accommodation for the proper conduct of various affairs of the Cardiff Corporation. The people of Cardiff are no doubt very wealthy, and we fear we must add very stingy. Just now it is desired to launch into expense for the benefit of some of the inhabitants, in the expectation that eventually the Marquis of BUTE will assume responsibility for the outlay. At present there is a desire to obtain plans and to expend 50,000*l.* on a building, but it is to be hoped the selection of plans or tenders will not be entirely left to the local authorities.

ROYAL INSTITUTE OF BRITISH ARCHITECTS.

AFTER the business meeting held on Monday evening, an ordinary meeting of the Institute of Architects was held, Mr. H. Currey, vice-president, in the chair.

The deaths were announced of Mr. J. S. Crowther, architect, Manchester, and W. C. Tuke, also of Manchester.

Examination of Building Stones..

A paper under the above title was read by Mr. H. W. Burrows. He described the modes of judging of and testing building stones, and considered their relative merits in regard of structural and weather-resisting properties. He classified the leading building stones under the heads of granites, sandstones and limestones, more especially referring to the two latter kinds in regard of their chemical composition, and the disposition of the components. Prior to adopting stone for use on a building, it was necessary to examine its power to resist disintegration by crushing, shearing stress or weathering. If the architect could visit the quarry and personally inspect the beds, it would be all the better. There were three principal tests, viz. mechanical, chemical and microscopical, the last of the three being the most important. As to the mechanical tests, the chief related to tests by crushing small cubes, the customary method being to take the mean of the results; but as the strength of a chain was represented by its weakest link, the factor of safety should be the sample which least withstood the strain. He then referred to the familiar experiment with bedding cubes on lead or pine when the test object was subjected to shearing strain. It was also advisable to test samples of building stones under the action of frost, artificially, as easily could now be done, in absence of actual freezing. Another ordinary test was to show the amount of absorption of water. Limestones and sandstones, for instance, which showed the same powers of absorption of water, proved very different in powers of resistance to crushing or shearing strains. A rough and ready knowledge could be got by simply eye estimate of the earthiness or friability of the texture of the different species, but as a matter of fact an inter-comparison of limestones and sandstones was of no practical use. Another mechanical test was to boil cubes in a solution of sulphate of soda and then weigh and crush them. But he did not see that any natural influence ever attacked stone in this manner. A closely allied test was to immerse cubes in a diluted mixture of 1 per cent. sulphate of soda with hydrochloric acid, which he also considered to be of no practical value. In regard of chemical tests, to which much interest now attached, he believed they were misleading unless supported by other methods of tests. Quarry owners often enlarged on the large amount of silica in the special products of their quarries shown by analysis. If this were conceded it would prove that sandstone was more durable than limestone or even granite, an hypothesis which was manifestly absurd. In fact, experience had already shown that the presence of silica, whether in large or small quantities, gave no criterion as to weathering properties. Cohesion of particles was the true test of a stone. Scattered grains of sand did not by any means improve the character of stone, the question being the disposition and not the amount of silica, and in this investigation chemical analysis was no guide. Samples of chalk, limestone and marble might be equally pure specimens of carbonate of lime and absolutely identical in analysis, and yet no one would elect to build in chalk when he could have marble or limestone. Having explained that the difference lay in the fact that the carbonate of lime was amorphous in chalk, semi-crystallised in limestone and crystalline in marble, he went on to refer to great variations in structure in crystalline stones. According to chemical analysis, stone crushed to powder was of equal strength with solid rock as far as its components went, and therefore sand should be classed as the most stable of materials. All this showed that cohesion of particles was of far more importance than the actual nature of those particles. The third or microscopical tests showed the manner in which the particles were built up. He then gave the method of conducting microscopical tests, which we need not recapitulate, and proceeded to show a large number of photographic examples of sections of stones by means of the lantern. The lecture was further illustrated by numerous diagrams and classified lists of building stones.

Mr. Percival Gordon Smith proposed a vote of thanks for the paper, which was seconded by Mr. Henry Dawson and supported by Mr. F. W. Rudler of the Museum of Geology, Mr. W. Topley of the Geological Survey, Mr. Harris, Mr. G. A. T. Middleton, Mr. J. M. Bryden and Mr. William Woodward.

The vote was passed by acclamation, and the proceedings terminated.

LOCKS AND SAFES.*

THE subject of old locks and their keys is one which has received a considerable degree of attention, and those which are noticeable chiefly for the beauty of their artistic forms have taken precedence, being treated popularly from time to time in illustrated periodicals. Modern inventions have also created interest, but interest of a different kind, more utilitarian—in fact, scientific. It need not, however, be taken for granted that the two views are incompatible, or, in other words, that a sharp line must be drawn, say, at the end of the seventeenth century, to divide the artistic from the mechanical. As a matter of fact the gradual growth or evolution of the locks in common use to-day can be traced, with but few missing links, from the earliest forms. Overlaying, and sometimes almost obscuring, the mechanical intention is the work of the artist, this being invariably characteristic of the period when the artist-worker lived. This is true no less of Roman times than when French and German smiths of the Middle Ages encrusted their lock-plates with Gothic mouldings and carved their delicately-shaped key-bows. As the styles of architecture and its kindred arts succeeded one another, age after age, the decoration and treatment of locks and their keys were affected by the same changes; mechanically they altered also, not, however, always for the best when looked at from the modern point of view. One cannot, therefore, say that their advancement in the two respects has been together, but the connection between the two is at all times interesting and often instructive. Mechanical invention, pure and simple, is just as much subject to the general laws of progress as everything else. So also is the work of the designer, mechanic and designer being equally inventors in the true sense of the word. When you have the two qualities combined in one man, as they were frequently in the Middle Ages, you get a result that is self-evident, and although it cannot be said that the progress then in craft equalled the progress in art, there is yet a greater harmony between the two than when they are separated, or in any other way specialised. Whilst the inventive faculty has had, and still has, so much to do with the locksmith's craft, this is hardly the opportunity to analyse it; but I think the axiom will be readily granted that, viewed broadly, it is not purely a matter of spontaneous genius or mere mental accident, but is, as I have suggested, a faculty admitting and responding to cultivation.

Before entering upon the subject proper of this paper, there is one minor branch that may be mentioned. I refer to the use of seals. The effect of the seal is an ethical one, as long as the moral tone of the community is good. The Egyptian storehouse keeper sealed up his large earthenware corn jars, using clay as the material to take the imprint of his matrix. One notable Biblical instance occurs when Darius and his lords sealed the door of Daniel's den. No lock was needed where the king's device had been impressed, and the king alone could undo his own work. The survival of sealing to the present day, for securing our Post Office despatches and Customs vaults, shows that where there is an obvious intention on the part of authority that certain things shall be left alone, that wish is respected. The use of a personal or corporate device, first and still employed as a means of identification and of legal power, readily lends itself to this purpose.

Amongst early fastenings, those intricately made by knotted thongs or ropes should not be omitted, for with these nomad pastoralists tied up their tents. The Gordian knot will, of course, occur to everyone in this connection.

No one has more clearly traced the early growth and sequence of lock mechanism from the primeval door than Lieutenant-General Pitt-Rivers. Doing for locks what he has done for weapons, for certain conventional designs, &c., his contribution to their history is of great value. Besides tracing their development, he has followed the various types along the known lines of early trade, showing how they became distributed.

The present wooden lock of Egypt—the Dub'beh—supposed on fair grounds to be the same as that used 4,000 years ago, has been illustrated and described so often that it is almost needless to do so again. That the two locks are identical is highly probable; the water-raising "shadoof" has remained through this long period, and there are other evidences of similar mechanical crystallisations in the East. Indeed, a recent description of a wall-painting in the temple at Abydos, given by the late Miss Edwards, almost proves the point. She

* A paper by Mr. Harry W. Chubb, read at the meeting of the Society of Arts on April 12.

writes of "Rameses II. . . in the act of opening the door of a shrine by means of a golden key formed like a human hand and arm." This closely agrees with the oft-quoted account—now 100 years old—given by M. Denon, of a painting in the great temple at Karnak, and both descriptions are true of the present day lock and key.

It is quite reasonable to suppose that the first barring of a door was done by means of a cross beam, either dropped into sockets or sliding in staples fixed on the door; and it is equally reasonable to suppose that if it slid, a vertical pin dropping into a hole through the staple and beam together, kept the beam in place.

If the beam was inside the door, and had to be released in order to slide it back, then one kind of key was necessary to take out the pin. Of this I shall speak presently. But if the beam was on the outside, then the locking pin must be hidden, and can only be reached either through a hole in the beam, or else through a hole in the staple. The Egyptians adopted the former method; other primitive peoples adopted the latter. They—the Egyptians—shortened the beam into a long bolt, and made it hollow for part of its length, so as to reach the pin, hidden in beam and staple through the beam itself. The key, which was pushed up the hollow, had pegs on it to match the pins which held the bolt—for the one pin was now multiplied. When the key was well "home," it was raised, and so its pegs lifted up the pins out of the way, leaving the bolt free. Then the bolt was drawn back by the key, the pegs of the latter filling up and engaging with the holes till then filled by the pins. You notice the shank of the key is the arm; the pegs are the fingers of the hand. We shall see how this principle of dropping pins—true tumblers—was adopted with variations by the Romans.

Now as to another class of primitive locks—those in which the pins were reached through a hole in the staple, and not through the bolt. There is good reason to believe they were once remarkably widespread, though now chiefly found on the fringes of culture. You see them at the present day in some parts of Scandinavia, in the Hebrides and Faroe Islands, and the peasant of Normandy still makes them for his gates and barns. They have also been observed upon the West Coast of Africa; and Herr Andreas Dillinger, of Vienna, whose name is known in Germany in connection with the historical study of locks, states they are in use in the less frequented parts of Galicia, Roumania and Servia. The hole in the staple by which to get at the pins is a horizontal one above the bolt. The pins are square in section, and are notched on their sides for the key to pass and get into position before being lifted. The key is usually flattish, with little side projections which engage the pins. After they are lifted it is necessary to pull back the bolt by hand, thus making a marked and essential difference between this lock and that of Egypt, in which the bolt is withdrawn by the key itself. They vary in detail, some having two sets of pins, the key passing between the sets; in others the pins have holes right through them for the key, not merely side notches.

The next two classes of primitive locks are those in which the beam or bolt was mounted on the inside surface of the door. In this case, if fastened by the tumbler pin, it would not be so necessary to conceal it as when both were outside the door. There are some curious sickle-shaped pieces of iron found now and again, which look as if they were made for the purpose of putting through a hole in the door, and pulling up or pushing up the pin. Perhaps they simply engaged the bolt in a direct fashion, and, being turned from the outside, moved it to and fro. But they vary in their outlines too much for this supposition to be probable, some being full sickle-shape, and others only slightly cranked or bent, and in some well-preserved specimens their ends have been carefully shaped, as if to fit a hole exactly. They have been found at many places in France and Germany. General Pitt-Rivers well authenticates some he himself found near Lewes to the late Celtic period. In connection with these he also discovered some coins cast in tin of debased Greek design, and points out how this shape of key agrees precisely with a description given by the Greek writer Eustathius in the twelfth century, who states that this kind, although still in use, were considered antique. This coincidence is extremely curious and interesting, and makes one wonder if the Phœnicians had been the agents of its distribution.

At last we come to the fourth primitive type of lock, the bolt or beam being still inside the door. In this type the bolt was kept out by the projection of a spring or springs, which spread out against the side of the staple in the same way that an unwilling boy spreads out his arms and legs against the jambs of a doorway through which his schoolfellows try to push him. The first function of the key is to compress the springs. It is a flattish one, with return prongs or hooks on its end. It is first passed through a horizontal slit in door and bolt, then turned a quarter-circle, and pulled. The pull brings the prongs to bear upon the springs of the bolt, making them lie flat, and so clear of the fixed obstructions at their ends. The bolt is

then free to slide back, and this is effected by simply sliding back the key, for its prongs are now embedded in the bolt. The keys of these locks are numerous found among Roman remains, and locks of this kind are stated to be in use still in Norway.

Having thus very briefly stated what is known of the primitive kinds of locks, let me take the last type, and show how closely allied its mechanism is to that of the Roman padlock. Looking at the diagram, you will see the lock consisted of two parts—a body and what, for want of a more accurate term, may be called a hasp or bolt. The hasp carries on its lower side a pair of spreading springs, and these enter a hole in the end of the body when the two pieces are being put together. When the hasp is pressed right "home," the springs, which during the operation have been gradually closed up, now fly out inside the body, and so hold the two parts together. To take them apart the springs must be compressed, and this is done by the key, which is pushed through a hole in the body against their sides near the point, and slides along them. The springs are simply flexible barbs.

It is no wonder that loose, portable locks, like those used to secure baggage of all kinds in transit, should become well known and distributed, especially along the ancient lines of trade. But as this style of padlock is found to be the almost universal one now in China, one is tempted to ask who was the first and true inventor, Roman or Celestial? They are seen, too, all over the East, being shaped and decorated in ways peculiar to their own countries. Here I have a modern Japanese of dragon-shape, two others with hidden key-holes, and a fourth—Chinese—in form of a conventionalised dog. His tail turns up right over his body, and goes through the back of his head, its end forming the tongue. This is the hasp. To release it, the key enters a hole in his chest, and you push the tail right out. There are some bodies of Roman ones in the British Museum like this Chinese curiosity, but looking more like horses than dogs. All these have the diverging springs. There is one in the Indian Museum in which, to close up the springs, the key is turned as in an ordinary padlock of the present day, not simply pushed in, and a large class of Mediaeval padlocks—French ones more especially—are made like this. The Romans had other kinds of padlocks as well, the security parts of which were made like those of their fixed locks. Here is a copy of one made from an original at Pompeii.

Now as to the Roman fixed locks. Many archaeological "finds" indicate what these were, but none so clearly as those unearthed at Pompeii. I will show you on the screen some specimens photographed by a friend for me in the Naples Museum, and you will see from these, as well as from the wall diagram, how closely these locks are akin to the Egyptian. The bolt is now much shortened, and is concealed behind a front plate; it is still held, when locked out, by vertical pins falling down into it. The parts are now mostly, if not all, of metal, sometimes in a wooden casing or block. The pins vary in sectional shapes, being oblong, square and triangular, as well as round, and are pressed down by a flat spring. The key has projections or teeth formed on it, corresponding to the pins, and reaches the bolt through a hole in the front plate. The pins being pressed up by the key projections, the bolt is free, and can slide to and fro, precisely as in the Egyptian lock. Roman keys are found much more commonly than their locks, and some are of such shapes that it is not always easy to say what their locks were like. There is a key with its "bit" angle shaped; one angle is cut to operate bolt pins in the way just now described, the other is pierced with holes, as if to pass fixed obstructions or wards. Many of the keys were undoubtedly turning ones, having solid stems called "pins," or else made with hollow stems called "pipes." The pipes were sometimes drilled right up, so that any dirt or other obstruction could be pushed through. I believe this simple device appears in three separate English patents, and not a year passes without some enthusiastic inventor rediscovering it, and offering to part with his idea for a consideration. Here are two old bronze keys of this kind, dug up in London. On the wall is a picture of one taken from Molina's "*De clavibus veterum*." This picture brings us to a class of Roman keys that is quite unique, and which, although well suited to present wants, is, strange to say, not in demand. These are the keys attached to finger rings. Whilst not found as numerous as those of other types, you cannot visit an antiquarian museum without seeing specimens of them. Their bits are as diverse as those of the larger keys. Here are five specimens on one of the show boards. These are replicas cleverly made after originals at Naples. A few only are found combining signets with keys on one and the same ring. It was the Roman wife to whom, as a bride, when crossing the threshold of her new home, the house keys were given. They were all here with one exception. That exception was the key that kept the wine. This her husband held. The hoops of the ring keys are all large, being of a size suitable for a masculine finger, and it is likely that they may have been specially for the locks that secured the wine amphoræ. Just now I suggested that it was a pity this

combination of ring and key is seldom met with in general use. Many years personal experience has shown me that it is an extremely convenient combination. The key folding behind the signet of this ring opens several locks *en suite*; there is less chance of losing it than on a chain, and its effect upon Customs' officers—even on a New York examiner—when produced to open trunks and bags is marvellous.

Here let me mention what there is bearing upon our subject among the objects recently found at Silchester, Hants. There are quite a number of iron hook keys of various sizes, with their prongs arranged in different ways; there is the iron hasp with barbed springs of a padlock, a bolt in bronze for a fixed lock, with perforations for triangular pins (this in very good preservation), and there are two of the neat little finger ring keys.

Coming down to the Byzantine period, one has to regret the absence of information about locks and keys. One need not wonder at this. "The empire preserved much, but did not add to the treasures of civilisation" (Garnett). In gold and silver work the Greeks still excelled, and the golden lions by the side of the throne of Alexius Comnenus, that sprang up and growled, no less than the mimic forest with automatic birds behind the throne, attest their mechanical skill. In all probability the existing forms of locks and keys, as regards mechanism at any rate, were adhered to.

I will now show you a few transparencies on the screen prepared from photographs of objects in the museum in Naples, very kindly taken for me by a friend. These will exhibit the characteristics of the Pompeian work. About the shapes and ornamentation of the key shafts there is no light Greek touch such as you find breathing through the higher forms of Roman art; still they have an interest of their own, and have not been previously illustrated.

At last, in the seventh century, and in the now more settled West, a metal-working personality appears, St. Eloy. He was probably the first to found what would now be called a "laboratory of art metal"; and this was in connection with his abbey. Three centuries later comes St. Dunstan, in early life working at the forge himself, and even later, when burdened with the heaviest cares of the state, still at his leisure fostering the growth of art in metal. Other great men, long since those times, have found relaxation in the blacksmith's art. I recently came across an old jingle, in which of Louis XIII. it is said—

Sometimes into his forge he goes,
And there he puffs and there he blows,
And makes both locks and keys.

This is said of him when he was young. Charles I. indulged his caprices in the same direction, and, later yet, Louis XVI.

With the commencement of the Mediæval period, we get to shapes of keys more like our own, and working more like them than the preceding types. The sliding and pushing have given place entirely to turning movements, the keys being either made pipe-fashion, to slide on to a fixed pin in the lock, or else made solid, and terminating in the projecting pin, which fitted a socket or hole cut in the back plate of the lock. Later on, the section of the pipe was not always circular; sometimes it was triangular, and the pin on which it was pushed was shaped to fit it. Of course, provision was then made for the pin itself to turn with the key. The outside of the key, too, was fluted, and the lock pin then became a barrel as well, revolving in bearings at both ends. But this is anticipating, for these varieties do not appear until Renaissance times.

One feels greatly tempted at this point to make an excursion into the wider field of metal-work in general, for it was then that the smiths' art began to take shape and prominence. Our study is but a small branch of the art not being specialised till modern times, and it is somewhat of a barbarism to strip off a lockplate from, say, a cathedral door, and show it alone. Unaccompanied by the graceful curves of the hinge straps that flow across the door to it, a good deal of charm is lost. With the introduction of the Pointed style in the twelfth century, the culture of ironwork, no less than of the other metals, begins to move side by side with architecture. The Church, becoming richer from her share in the world's increasing wealth, secures not only the services of the best laymen, but increases—especially in France—the number of her monastery schools in which the arts were variously taught. From these emerged many a masterpiece in iron, silver and gold, fashioned by hands that were guided not more by art feeling than by a love for the sacred edifice the work was to adorn. Besides, there was plenty of time to do what had to be done: lives of hurry were unknown. Even in those days the results were not taken as matters of course. They excited admiration and wonder. Witness for instance the compliment paid to Biscornette, a layman, the maker of the hinge-work for the doors of Notre Dame, Paris. They said he could never have produced anything so beautiful without the devil's help. Perhaps professional jealousy started this rumour; if so, it was all the more a compliment. At any rate he disappeared suddenly one day, and the secret methods he had discovered died with him (Burty).

These very early keys have their humble bows in symbolical or, speaking generally, in ecclesiastical shapes—trefoils, quatre-foils and the like. Most remaining to us are of bronze, and, like many of the finely wrought iron specimens of later date, have thus escaped the melting-pot that, from time to time as coffers got empty, engulfed art-work made in the more precious metals. Here is one with an almost spherical bow, pierced. This early lock is the ancestor, in direct and unbroken line, of the ordinary tumbler lock of to-day. It had a bolt prepared by a notch for the key to actuate—locksmiths call this notch a "talon"—and it was held in place by a tumbler. The tumbler, instead of moving vertically, was hinged. The word "catch" describes it better than tumbler. A part of it came down over the bolt to reach the key, and the first thing the key did as you turned it was to lift up the catch, then, as you went on turning, the key caught the bolt in its notch and moved it. The wall-picture, with the sliding door bolt, is one of these. You will notice the bolt has a hasp or tongue coming off at right angles to it, and this enters the lock, and is there secured by the internal bolt. Liger, I think it is, ascribes these locking bolts to the thirteenth century. You can see them on the cathedral doors of Chartres, Rouen, and in some of our own cathedrals, and I once met one in a very unexpected place. This was on the door of the inner temple building at Kandy, where the piece of ivory called Buddha's tooth is kept. Presently I will show you a photo of it. The surface decoration of the lock has nothing Gothic in it, and it did not look imported, but no one knew its age. Within the same building was another surprise, the iron grille surrounding the tooth itself being fastened with two Chubb's padlocks.

Besides these thirteenth-century locks with the single tumbler, those with fixed wards were in use, their keys showing numerous and intricate slits and perforations to pass over and around them. Warded locks appear to have been the chief kind used for many centuries. Amongst the primitive we found four types; at this stage we have but two, the letter padlock does not come until the commencement of the seventeenth century.

Certainly the most beautiful specimens of keys are those we now meet with belonging to the fifteenth and early sixteenth centuries. A good specimen authenticated to 1530-70, and now at Frankfort, is shown in diagram. Others in the Florence Museum I will show on the screen. There are a few at South Kensington, and some in the Musée Cluny. For perfect proportion in all their details and minute workmanship, they have never been excelled, even by the later Renaissance keys. Their four sidedness and breadth gives them a strong, sturdy look; but this is lightened by the gracefulness of their pierced tops and sides, allowing the same play of light and shadow that you get through the tracery of a Gothic window. Hence flat pictures alone do not show their beauty; you must see them in order to be able to appreciate them. Of course they are awkward to hold, and you could pick their locks; but such criticisms are the property only of the nineteenth century—the century which commenced by making roses, flowers and branches in cast-iron for suburban villa gates, and has not quite got out of the habit yet. Now, also, we get the highly-ornamental lock-plates of French and Flemish make, the Italians devoting themselves chiefly to the adornment of sword-hilts and other articles. The French locks, and even escutcheons, showed considerable skill in adornment. The mouldings of the traceries upon them are made of layer upon layer of saw-pierced plates, one plate on top of another, their edges forming the members of the miniature mouldings. Where there are no figures or other devices, to which the traceries are only secondary, there is sometimes a background of brass. This gives a contrast in colour, and adds effect, for traceries are primarily intended to be seen by transmitted, and not by reflected light. If by reflected light, then the mouldings must be deep, so as to give rich shadow.

The German work of this period excelled more, from the artistic point of view, in the decoration of their lock plates than in fine keys. To begin with, the outlines of the plates are more fanciful. The surface decoration of the plates consists of a single thickness of metal, cut out and embossed to represent conventional flowers and fruit growing on stems that branch out gracefully from below the keyhole. The converging branches thus form guides by which to find the keyhole on a dark night, or when, from other causes, it was difficult to hit upon it (Wyatt). Recently this idea of external projecting guides to a keyhole was patented in England. There is an interesting thing about these German lock-plates that partly accounts for their shape. Their bolts were generally spring ones, and to get long—though not always easy-acting—springs to act upon them, the end of the plate was made much wider, in order to hold and cover them. Hence, you see, there is a direct result of form springing from utility. You can see it in these old German locks I have here, obtained in Nuremberg. On another board is a copy of a Japanese lock-plate of similar shape, but this shape, though common to many Japanese locks, is not, I think, owing to the same cause. One can tell to what

extent the Germans prized their pretty plates when it is known that their owners carried them from place to place when changing residence (Labarte).

(To be continued.)

PHOTOGRAPHY IN RELATION TO ARCHITECTURE.*

IN the course of his address, Mr. Allport asked, What is architecture? The art and science of building. It is rendered imaginative by the architect as delineated on paper or by models; or real, as executed in buildings. It comprises all the sister fine arts, as painting, sculpture and music. It therefore takes the highest standpoint in the fine arts. Yet the author conceives that photography must be satisfied with a comparatively low position, even though there be much scope for mind and imagination; for when compared with the art of architecture, its scope is dwarfed considerably; for true art lies in the architect, painter, sculptor and musician; not in the pencil, paint, marble, stone or instrument; in the man and not in the means. So the higher phases of photography lie, in a sense, in the acquired skill of the photographer—his choice of subject, his knowledge of light and shade—rather than in his camera and chemicals; in fact, in other respects there is more of artifice than art in photography, and it is an art shared in common with artisans, and a fit companion as such with arts and crafts. Such being the case, as soon as photography offers equal facilities as with architecture, painting, sculpture and music for expressing one's ideas, then, and then only, can any approach to equality be claimed. It is necessary to focus so as to obtain the finest effects of light and shade with a certain amount of depth, bearing in mind that too great depth will produce hardness of outline, whilst a medium depth will give that requisite artistic feeling and degree essential to convey to the mind the relative projections of the object, the definition and details of the buildings photographed. Whilst this will apply to all works, it has a particular bearing upon studies in architectural art and craft; and will intensify feeling, and give a vast help in the balancing of lines, in unity, breadth, repose, &c., which, taken together, form one grand whole.

It will be well to consider the various heads under which to the author's mind photography is of great practical use to architects, architectural students, and the constructive engineer; to surveyors, sanitary surveyors, and the lawyer—in fact, to all persons who have to deal with architecture and its practice. This granted, photography becomes a very material and important adjunct to the study of architecture both in theory and practice. And in the exemplification of architecture, through the medium of lantern slides, it may of course be regarded as indispensable.

1. It affords to the architect and student the advantages of seeing faithfully delineated architectural examples and subjects both of ancient and modern works. This conveys a guidance to their study which no other means with equal truthfulness affords. Thus, too, it becomes the medium of creating impressive comparisons of different treatment of architectural subjects of all ages and climes.

2. It allows architects to have copies made of their own drawings, whether they are sketches, studies or works to be executed. These, it need hardly be remarked, can now be reproduced by many processes in use, such as photogravure, photo-lithography, zincography, calotype, bromide, carbon, Woodbury, platinotype and other systems.

3. It affords the architect and architectural student the opportunity of carefully comparing the effects of various designs of buildings that have been published or executed, and allows them to make a comparative analysis, either for study or to enable them to judge as to what, in their opinion, is good and to be followed, or rejected as bad or inappropriate for their purposes, or present requirements in the working out of their designs.

4. It offers to the architect and student the advantage of making combinations from photographs of works and designs—combinations which they could not effect by the mere inspection of a building or by making casual sketches, even if time and opportunity permitted. This especially applies to examples of elaborate and intricate designs and works.

5. It enables the architect to take or have taken for him photographs of the buildings he is erecting. This practice is being extensively adopted, and no doubt will be more generally utilised in the future, either from an artistic or practical point of view, and with the following objects:—

(a) Photographs of existing buildings before their removal from the site to be utilised in the erection of new buildings, or to show damage or destruction done to them after the effects of a fire, storm, &c.

(b) Photographs of adjoining buildings showing relative position to buildings to be taken down, particularly as to light and air enjoyed previous to the building being removed either by building or adjoining owner. The neglect of this is often of serious importance and a cause of loss to the parties affected.

(c) Photographs of works in course of erection for such purposes as that of showing their state at certain dates for granting certificates, and also for keeping a record of works in course of erection, or of defective works done by builder, or the state of works before removal of any portion for intended alterations during their erection, or as exhibits to a client who may be far removed from the locality or abroad during the execution of the work at its various stages. It is quite possible, too, that the building owner might employ a photographer privately as a check upon both architect and builder!

(d) Useful indeed are photographs of building construction, particularly those of iron and steel, both as a record of their condition during manufacture, and at the building during fixing, or of sections and showing qualities, &c., after the effects breaking from the result of tensile strain or breaking loads, and after completion. These prove a very interesting and instructive medium for instilling into the minds of pupils and students a knowledge of quality of materials for, and in connection with, the principles of construction, particularly so in the absence of the opportunity of visits to the workshop or building during the preparation and fixing of works of this nature, and where details of construction are concerned.

(e) To the pupil and student photographic views of works in these several stages of progress enable them to thereby keep a record of what they have seen executed, to note defects, advantages or disadvantages, in a manner that cannot otherwise be so comprehensively obtained except by great labour, loss of time and expense. They also enable the pupil to have a record of what he has seen in its embryo condition on paper in the office until completely carried out in the building itself.

(f) To the architect and surveyor photographs of existing buildings taken before being interfered with are very essential, especially when taken under different lights and at various hours of the day. These, in light and air cases, will often save a client from serious litigation, and, when the latter cannot be avoided, may be the means of protecting him from heavy loss, damages and much anxiety, especially when used as rebutting evidence in legal cases of this kind, as in connection with dilapidations, dangerous structures, &c.

(g) To the architect, architectural student, antiquarian, surveyor and the sanitary surveyor. Photographs of important drawings which have passed through their hands can be taken, and any subsequent alteration of a detrimental or fraudulent nature subsequently made can be readily discovered. The same remarks equally apply to written or printed documents, of which time perhaps would not permit copies being taken by any other means. These are vouched for as accurate, and are often found to be of no more reliable and trustworthy proof than that of evidence given by experts as to handwriting, &c.

(h) For architects of large and elaborate buildings, who are in the habit of employing eminent sculptors or carvers to execute works from designs, models of their own, or direct from their own ideas and imagination, photographs of such work can be taken from the scaffolding so soon as executed. This work is often at heights and in such a position as to render it difficult or impossible after the removal of the scaffolding to take photographs of it. These often prove of great service in that they enable the architect to have the photographs taken with a light and shade, giving a definition from an artistic point of view not only as a record of what has been executed, but of the effect produced. They also help him to form an opinion of what is good and effective for future execution, and to avoid anything that has proved unsatisfactory.

Very much more could be advanced under general heads of the advantages of the use of photography by the architect, architectural student, architectural and sanitary surveyor; whereby matters of doubt can be solved and information obtained in the office in a few minutes by photography which might otherwise require days, weeks or even months to accomplish, and in some instances might never be obtained.

The author, speaking from the short experience of an amateur of two years' standing, could enumerate many instances of the great advantages he has already derived from the use of his camera, and in some cases its requisition has so unexpectedly arisen in urgent professional matters as to be of great importance to clients and himself; of these, however, he could not give anything like detailed particulars in a paper so limited as this.

To those who wish to qualify as amateur architectural photographers, whether out of love of art or of the numerous advantages derivable therefrom, it may be said that without good tools and appliances they will not obtain any satisfactory results. Having decided upon the size of plate to be adopted, let the camera be a special one for architectural subjects.

It must be rigid, and have a perfect turn-table, with a swing

* Abstracted from a paper read at the meeting of the Society of Architects on Tuesday, April 18, by Mr. William Allport, F.S.I.

back and cross-levels thereon, and it should extend forward and backward at least 30 degrees each way, for absence of distortion is a *sine quâ non* in recording facts. Especially should the turn-table be set perfect level, and the front and back fixed at right angles with it, otherwise the neglect of this in the using of the turn-table is apt to cause distortion if the camera is slightly altered either way.

The author's is a whole plate one, but so arranged that half or quarter plates can be used when so desired, thereby allowing double the number of views to be taken when using whole plates only. The lens should likewise be adapted for architectural matter capable of giving a clear and the finest definition possible, with parallel lines in every direction. The one now in use by the author is a portable symmetrical lens, which when properly focussed and adjusted gives excellent work and affords a good definition and flat surface. This lens is now superseded by a more recent one, called the patent concentric lens, absolutely free from distortion and imperfections incidental to lenses of general construction, and giving a still finer definition than the portable symmetrical lens does. Another important departure in lenses is the production by Mr. Dallmeyer of one that will give an object thirty miles distant. This, of course, is dependent on a very clear condition of atmosphere, and not such as appertains to this country in general or this metropolis in particular; but nevertheless it will, even in this country, take views of any buildings many miles removed. Time will not permit the author to go into all the details and requirements to enable a novice to become an amateur photographer or describe the various *modus operandi* of the science, or as to the most approved camera for architecture or plates, time shutters, dark room, ruby lamp, developing trays, dishes, chemicals, focussing, exposure, developing, varnishing, printing, toning, mounting, &c., or the making of lantern slides and other incidental accessories too numerous to mention, let alone entering upon their detail. There are now so many able works to be had on these details, and the information afforded in them is obtained from such well-known and reliable authorities, and the ready means are now so available for obtaining practical lessons, that these will afford a more satisfactory road to becoming an amateur architectural photographer than anything the author could bring before you at the present time, and he therefore proceeds to give you, through the medium of lantern slides, some examples of ancient and modern architecture.

A civil engineer writes that the use of the camera, both theoretical and practical, ought to form part of the education of the civil engineer; and he tells the old story of the engineer who every morning received progress reports of an important work many hundreds of miles away from him by means of photographs. This embodies all that can be said for the use of the camera to the civil engineer. Why, then, may it not be equally applicable to the architect in his profession and wanderings? The architect may often come across fine examples of architrave mouldings or other architectural details which may prove of great use at some future period when he is designing a building.

Instances of this sort might be multiplied *ad libitum*, but, given the idea as here attempted, architects, like engineers, will be able to discover at once where the camera may be useful.

It must not, however, be supposed that the author for one moment decries the practice of sketching, or would substitute for it the use of photography. The necessity of being able to sketch even moderately well must be admitted by every one as a great essential to all architects and architectural students.

In these times, however, of high pressure and necessity for quick despatch, particularly in this metropolis, photography is an important adjunct to architectural practice, and, as has been said, can be used with very considerable advantage by the architect; for instance, when on a tour, many objects of architectural or antiquarian interest often present themselves that time or circumstances will not permit of his sketching, but of which by means of a camera he is enabled to obtain views in a short time, and that under effects of light and shade it would be otherwise impossible to obtain.

Take, for instance, an elaborate entrance to a cathedral or a building at an inaccessible position or height. Even though a general view only of the whole of a building can be taken in an expeditious manner by the photographic amateur, it allows the sketcher more time for details, and for taking careful measurements of parts of interest necessary for applying in any works of a similar kind, and for adapting them to his own designs, and the effect of which the architect is enabled to form an opinion upon from his general photographic view. Therefore, to the architectural student let it be said, be as good a sketcher as possible, even though you aspire to become likewise an expert amateur photographer, and do not permit your art as an architect to degenerate into a mere photographic copyism.

As to the use of photography in connection with lantern slides for demonstrations of architectural subjects, the illustrations we have seen this evening fully show what a powerful

agent and adjunct it has proved to be in connection with photography in the development of architectural art, and in the illustration of such papers as are given from time to time by this Society.

The author is of opinion that a great advantage and good service would accrue to the profession in the establishment of a "National Architectural Camera Club," having its headquarters in London, with the view of fostering the development of architectural study and design. Especially would this be useful to the student and profession in the provinces, for the latter have not the same opportunity of acquiring knowledge and information as is enjoyed by those resident in this metropolis. Through the medium of such a club or society a department might be added for the exchange of architectural photographic views and the lending of lantern slides for lectures. The author will be pleased to co-operate with any in the profession with the view of establishing some such club or society in connection with the Society of Architects or any other architectural body in the metropolis, and has already mentioned the object in view to the promoters of a proposed "Central Photographic Club."

As an off-shoot to photography, as an adjunct to architectural art, examples of sun printing of copies from tracings of drawings and of architectural and engineering works can be made by the ferro-gallic or black line process, by which most useful and accurate reproductions of original drawings have been obtained. Examples of designs, working drawings and details are exhibited on the walls of this lecture-room. Many of these are tracings made by ladies and printed by the proprietress who presides over them.

And now a natural question presents itself for the consideration and discussion of this Society. Is amateur photography of any material benefit towards the advancement of the art or to the architect, engineer, student or surveyor, or is it to be looked upon as an amusing and fascinating pastime only?

The author of this paper puts forth for the Society's consideration, and that of the amateur in architectural photography who brings to bear a seeing eye and an understanding heart, that while it is not difficult to make a photograph, it is quite another thing to produce a satisfactory picture. To obtain the latter he must exercise to the fullest extent at all times the power of recognition, discrimination, and a careful selection of subjects, and with a wise, patient and attentive eye he will have to select his predominant object, and with varying aspect, and selecting a proper time that will ensure judicious light and shade with the requisite half tones. It is with these important and necessary adjuncts that the higher uses of photography can be best and advantageously employed in developing the beauties of architectural art, and thereby be enabled, through the medium of the lantern slides, to demonstrate them to the architectural student and lover of our noble art.

Does not photography materially therefore assist us in our guidance and judgment in architectural art, just as a fair criticism is a union of knowledge with self, and is it not so as respects photography in its relation to architecture, and indeed with all creative art? In this way does not the study and practice of photography lead the way to a fuller inquiry into, and comprehension of, architectural art, and by that means materially assist in the formation of a finer critical faculty, and in a sense giving to the mind forms and ideas communicable, just as languages do? And is not photography in a measure the conducive means to a better all-round excellence in architectural design, and thus give force to the creative power of the mind which, when well directed through the aid of photographs of good examples, will be materially assisted? It is towards a right direction of ideas that the advantages of good criticism will thus tend; in short, the architect and architectural student become better masters of their art and free from monotony of style.

SYMBOLISM IN ART.

A SERIES of lectures are in course of delivery by Mr. John Macdonell, LL.D., at the Royal Institution on Symbolism. After referring to the spontaneous expression of inward emotion by external gesture and the varieties of such expression which were found in different nations—adoration, for example, being indicated sometimes by kneeling, sometimes by raising the hand, and in other cases by kissing the hand or some sacred object—he pointed out in his first lecture that the extremes of passion were sometimes expressed by the same action—as in the instance of excessive joy or grief. The symbolism of different parts of the same country was sometimes entirely different, and a Lombard would find the gestures of a Neapolitan unintelligible. It might be even contended that writing was a debased or latent symbolism, and there were conditions in which it was a very inadequate form of expressing thought. One striking symbol of impossibility was two feet walking upon water. Then marriage ceremonies were often a reproduction of the forms of capture or of sale and purchase. A large region

of the subject was embraced under the head of colour, which in all ages and places had been used as the vehicle of expressing moral and æsthetic ideas. The lily had been a favourite token of purity, and the Blessed Virgin was traditionally always represented in blue raiment. Goethe had treated exhaustively this branch of the history of symbolism in his "Farbenlehre" and shown the associations which had most generally prevailed between particular colours and special emotions. Sickly yellow was, for example, the vehicle of contempt, as in the case of the Jews, who had been compelled to wear that colour. Our mystic poet-painter Blake had thought out, and particularly in his "Marriage of Heaven and Hell" realised, precise conceptions of the ethical value of colours. It was the function of poets and painters to translate the impressions of one sense by means of another. Diderot was fond of speaking of "sonatas in colour." Both painters and poets showed unmistakable preferences for particular colours, but the remarkable thing was that they were by no means the same preferences. Among the painters there was a generally prevalent choice of red and blue among other colours, whereas the poets of many ages and nations—Euripides, for example, Shakespeare, Spenser, Wordsworth, Tennyson, Matthew Arnold—found their epithets chiefly in white and yellow or gold, and the red and blue of the painters were relegated to a subordinate position. This interchangeability of different sensations was well expressed by Goethe in his simile of the three rivers having their common source in one mountain. It often happened in the history of language that words originally used in connection with one sense were extended to another. Another group of symbols consisted of tangible objects. Thus a sword represented a man, a spindle a woman. Among the Romans an auction was denoted by "hasta"—a spear—a term probably derived from conquest. In many tongues the hand intimated power and protection, and the glove always denoted protection. Certain birds and beasts were also invariably endowed with a symbolical meaning. The elephant was naturally used for wisdom and the lion for strength. The hare indicated timidity, the falcon vigilance, whilst the eagle was the bird of Zeus. Disastrous consequences might follow from misunderstanding the symbols of a savage tribe, as was done by the French navigator of the last century who accepted the brand from the Tasmanian, thereby, though he knew it not, taking up a challenge to war. In the case of great literary nations symbols became of world-wide range, as in the case of the club of Hercules, which in some instances had been confused with the hammer of Thor. The world was full of dead symbols, and virtually the same symbol played many parts. Who could doubt that the lituus of the augur, the crook of the shepherd, the staff of Æsculapius and the sceptre of kings all sprang from a common original? The lecturer also dealt in some detail with the forms of primitive conveyance by the handing over of a clod or piece of a tree or opening a door—forms attested by the enfeoffment and seisin of our English law—and illustrated the principle by drawings from early Anglo-Saxon chronicles exhibited on the wall.

In his second lecture Dr. Macdonell began by illustrating two important groups of symbolical ceremonies—those which are imitations of the acts to which they refer, and those intended to show in a dramatic way a change in condition or status. The Roman slave, for instance, might be freed before the Prætor by receiving a slight blow or tap, and being turned round. The Mediæval serf was often freed by *manumissio per denarium*. He held in his hand a coin, which was struck out of it so as to make it fall at the feet of the king. Sometimes he was freed in the churches by the master putting his hand on his head; and when in later time writing was employed, the writing was put on the serf's head, as if to show the words alone were ineffectual. When there was no clear distinction between things secular and religious, sacred and profane, the gods were often called as witnesses to the acts of men, and were even made parties thereto—a habit which in Christian times developed into elaborate forms of anathema inserted in ordinary legal instruments. In every well-drawn charter were several species of penalties—pecuniary, excommunication, divine judgment, with pointed reference to Judas, Korah, Dathan and Abiram. The lecturer cited in illustration a commination clause from a charter of A.D. 634. No usage had been more prevalent than the blood covenant—that is, the contracting parties drinking blood drawn from each other's bosoms, and references were given to this practice from Herodotus to modern times. The Scythians made their oaths by dropping blood taken from slight wounds into a bowl of wine, into which were dipped a sword, arrows, a battle-axe and javelins, and the bowl was then drunk by the contracting parties. In Central Africa much the same custom is still found. In tracing the wide prevalence of customs of this character we seem to be in the presence of a fundamental fact of human experience, an impression forced upon all races, that blood, the mysterious source of life itself, is the aptest emblem of a promise to be kept even unto death. After reviewing the various forms of marriage ceremonies—forms of capture and purchase, pouring of lustral water on the bride, eating bread

together, the married pair sitting side by side on the skin of an animal slain in sacrifice—the lecturer proceeded to examine the details of the English marriage service, and showed that it was a mixture of ceremonies, some of them symbolical and ancient, and that there could be found in it traces of primitive practices common to all Aryan nations. Before the time of writing most of the affairs of life—adoption, the doing of homage, the administration of justice, for example—were represented by symbolical rites. Somewhat akin to these is another kind of symbols—the signs or marks to designate beings real or legendary—what may be called the heraldry of mythology or legends—the symbols of the gods of Hellas, Rome, Egypt, and, equally numerous, those of the saints. Certain ceremonies served in lieu of statements of abstract principles. The coronation ceremonial was in a sense the constitution of a country. Not by the bare words of a written constitution, but by visible forms, by a striking and dramatic pageant, people were taught what their sovereign is and ought to be, and what are his rights and duties. In mythology, and indeed in all arts, there is a process of elimination and selection until loose, floating ideas finally crystallise in the aptest form. The free gestures of individual adoration stiffen into a liturgical formula; the unprompted prayer hardens into the form from which there must be no variation of a syllable; the rude, shapeless stone of the idol is gradually moulded into beauty. But at the moment of artistic perfection the symbolic element has almost departed.

ANCIENT MONUMENTS OF EGYPT.

A CORRESPONDENT of the *Times* at Cairo writes:—In calling attention to the following subject I trust I may not be understood or be thought to find fault with the remarkably able way in which the Gizeh Museum and the departments of antiquities connected with it are administered under Mr. De Morgan, to whose courtesy and energy I wish to pay my tribute. As, however, much of the cost of clearing the remains of the ancient buildings is paid for either by the tax on tourists—a large proportion of whom are English—or by the Egyptian Exploration Fund, it may be permitted to an English traveller to point out, through your influential columns, the serious and unnecessary destruction which accompanies some of the work of clearance.

At Kom Ombo, as was the case around so many ancient structures, a vast amount of *débris* has accumulated through the lapse of centuries. Both inside and out the building has been nearly buried. On the top of this *débris* many of the stone roof beams and slabs have fallen. This *débris* is now being removed. To replace the fallen stones in their original position would be a work of such great cost that it could not be faced, but to remove them by breaking them up seems nothing short of barbarism. This is, however, the course adopted. In order that the floor may be cleared, stone beams 10 or 15 feet long, and decorated with hieroglyphs, are riddled with wedges and then beaten to pieces.

The great difficulty of dealing with these vast masses of stone must be at once admitted. So far as my observation goes, supported by the opinion of others who are acquainted with building operations, it would not be a very hard matter to lower these stones until they rested on the floor of the temple, and there they would remain, bearing the evidence of what they were on their face. Whatever could by any possibility be preserved would then be preserved. To the student of archæology and architecture the preservation of these pieces and of all the evidence which the building can give is the only course that can commend itself.

In his work upon the temples and pyramids of Gizeh, Professor Petrie calls attention, with regret, to the destruction of similar beams by Mariette at the Granite Temple near the Sphinx, "when clearing up the place to exhibit at the festivities of the opening of the Suez Canal." Have not the tender mercies of the archæologist advanced since then?

I would urge upon those who have the administration of the funds that our very willingly paid contributions should not be expended in making the places neat and trim, but in preserving every stone that can be saved. One feels convinced that the present director of the museum, who is so deservedly popular, cannot have given his sanction to the destructive methods of procedure to which I refer.

At Der-el-Bahari I regretted to see stones being broken to pieces. No doubt the work of clearance would get on much more slowly were the stones laid on one side and preserved, but it must be remembered that to obtain a speedy result is not the one object in view.

The stones fallen are in many cases in as good a state of preservation as those still standing in their places. It is an open question whether in some cases the stones should not be once more set up, and thus a fresh lease of life given to the structure. No conjectural restoration is needed or should for a moment be tolerated.

RAEBURN AND SCOTTISH ART.

A LECTURE in connection with the Aberdeen Artists' Society was delivered by Mr. J. M. Gray, the curator of the National Portrait Gallery, Edinburgh. He said that though his lecture was mainly on "Raeburn," it also would include a brief review of the history and progress of portraiture in Scotland from the earliest times. The objects of the fine arts were to give pleasure; and these aims were attained by a dexterous and beautiful arrangement of the materials with which each art was specially worked. The most distinctive and especial pleasure which was derived from drawing came from its beautiful and specific arrangement of lines; and the first and most distinctive pleasure derived from painting came from its beautiful and satisfying arrangement of colours. But beyond this purely sensuous pleasure which was derived from a work of art—the result of technique and dexterous use of materials—another source of pleasure lay in its external and emotional power, and the power which it possessed to originate in the spectator a certain definite mental conception. This was a power that was common to all the fine arts, though each of them had its own special aptitude, its own special range of mental impressions for the production of which it was especially fitted. But in addition to these qualities of technique and adequate realisation of mental conceptions, there were other ways in which certain works of art might help them and interest them and give them pleasure. For instance, they preserved and recorded a fact, and portraiture did this; and while it might have very little sensuous charm or very little technical power, it might be useful as a record, and this was the main value of art. After dealing with certain of the early sources of portraiture, such as charters, coins and monumental effigies, Mr. Gray went on to speak of painted portraiture, and mentioned as one of the earliest specimens the altar-piece of Trinity College Church, Edinburgh, now preserved in Holyrood. He said there seemed to be no doubt that this was painted by Hugo Van der Goes, and it showed portraits of James III., his son, afterwards James IV., of Queen Margaret of Denmark, and of Sir Edward Bonkill, provost of the church. After referring to the portrait of James IV. at Keir, and the double picture of James V. and his second wife, Mary of Guise, in possession of the Duke of Devonshire, he went on to discuss elaborately the portraits of Mary Queen of Scots, mentioning the characteristics of the genuine portraits, and dealing with them according to the various periods, beginning with those painted and drawn in France. None of these could be assigned to the period of her residence in Scotland, but certain of them were known to have been painted during her imprisonment in England. Others were painted as memorial pictures after death, one of them being in Blairs College and another in the Queen's possession at Windsor. The only other authentic portrait was the alabaster effigy on her tomb at Westminster, erected by her son. After mentioning some lesser-known and intervening painters, the lecturer went on to consider in more detail the works of George Jamesone, of Aberdeen, giving a sketch of his life; Aikman, Ramsay, the pencil drawings of John Brown, and the medallion portraits of Tassi. Mr. Gray then sketched the early life of Raeburn, who, he said, was one of the swiftest painters known, and none had been able to give them more truly and effectively the counterfeit presentment of a man. Raeburn contemplated his subject from a distance, and discovered forms and contours that would otherwise have been lost sight of. He was an artist of the highest natural endowments, but he was interested in a thousand things beyond the pale of art. Housebuilding and shipbuilding, gardening and mechanics engaged his attention, and it was avowed that he was even interested in the intricacies of the law. Amid thousands of varied demands upon him he was a broad-natured, genial man of the world, enjoying life in the midst of a wide circle of widely-varied friends, and, as one of them remarked, nobody would have ever imagined him to be a painter till he took up brush and palette. No other painter was so exclusive a painter of portraiture as Raeburn. He was not like Gainsborough, who went into landscape, or like Velasquez, who went into the paths of sacred art; he left behind him absolutely nothing but portraiture—portraiture superb of its kind. No one could deny that Raeburn did not devote himself quite unreservedly to art. He was a great painter, who might have been a yet greater; and instead of remaining in absolute and effortless supremacy over Scottish artists that surrounded him, he should have settled in London and pitted himself against stronger men, and then perhaps an impulse might have come to him that was needed to force into living activity the very highest potentialities of his artistic nature. No Scottish painter was worthy to stand by his side—the only other artist that was fitted to do so was David Wilkie. Mr. Gray said he had not time to deal with modern portraiture, but Scotchmen now living, in the hands of their great townsman, Sir George Reid, and men like Orchardson and others, were maintaining in a high degree the efficiency and artistic beauty, and there was no prospect they would fail to leave behind them sufficient record of their visible appearance.

ARCHITECT'S FEES.

IN the Liverpool County Court, Mr. J. Havelock Sutton, architect, sought to recover 55*l.* 7*s.* from the proprietor of a restaurant for professional services in supplying him with plans for alterations and the addition of two storeys to the old Southern Hospital, Sefton Street, Liverpool, which had been used for some years by the defendant as an emigrants' boarding-house. The defendant paid 2*l.* 2*s.* into court, and denied further liability. The plaintiff stated that the defendant gave him orders to prepare the plans in question, and that they were duly delivered and accepted. A witness stated that he saw the plans delivered to the defendant, who expressed his satisfaction with them. The defendant denied that he had given the order for the plans in question. The judge having heard the case, said that on the evidence before him the plaintiff had clearly made out his case. Judgment would therefore be for the plaintiff for 53*l.* 5*s.* and costs.

The Future of Architecture.

SIR,—In referring the other day to the important architectural assistance the Persians gave to the Romans in the middle of the sixth century, I did not think it necessary in a short letter to notice other ancient examples of eclecticism. As, however, the history of architectural styles shows that every one with which we are acquainted was originated from some pre-existing germ or some model on which masons or trained artists had been working for generations, as in the example noticed above, I will now record one or two others, and conclude with a suggestion as to the future of architecture, or as I should rather say, as to the revival of a living spirit of British architecture, which is now in a melancholy state of coma.

But first to describe very briefly what the Roman army, every man of which was an artificer if not an agriculturist, must have seen in Persia about A.D. 500, just before Justinian decided to build a magnificent Christian church at Constantinople. When 200 years previously the Sassanian Artaxerxes and his successors, having conquered their enemies, were able to turn their attention to peaceful arts, architecture throughout Western Asia was at the lowest possible ebb, and it must have been with some difficulty that they gratified the desire, common with all powerful monarchs of the East, to exhibit their greatness by means of splendid buildings, although the stately character of the palaces of Darius at Persepolis must have been pretty obvious. But utility rather than magnificence seems to have been the object of the Sassanians, and consequently they adopted for guidance the comparatively insignificant buildings in Mesopotamia of an Arab dynasty, which generations before had ruled under the Parthians. The result proved that centuries of foreign invasion and oppression had not extinguished the art instinct of Iran. An architecture was developed which was so bold and magnificent that the Greeks and Romans of the sixth century deigned to imitate it. The main features in M. Flandrin's illustrations of the palaces at Ctesiphon, Serbistun and Firuzabad are entrance-halls 40 to 50 feet wide and 80 to 100 feet high, roofed over with an arch, and chambers on three sides communicating with one another and the hall, covered with domes of oval section. Contemporary historians describe these features and the walls as decorated with rich faience, in harmony with the national religion of Zoroastrians, and in the representations of Ormazd and Ahriman—principles of Good and Evil, and of the sun, moon and stars. Gold, silver and colours were freely used.

The Saracens having conquered and converted the Persians freely adopted the arts of their highly-cultivated subjects, but soon made the characteristic changes creating their own new style. In a wonderfully short time this noble race, no less energetic in peace than in war, founded cities, displaying their beautiful architecture not only in Asia but in Europe, Africa and India.

The Lombards applied the spirit of architectural eclecticism more boldly perhaps than any other race. Their structures were based upon Roman remains, but Greek workmen from Constantinople had great influence with them, with the result that the style is distinguished by more variety than any other. The round and the pointed arch, the Byzantine dome, the quadripartite vault, the Arabian minaret, towers square, hexagonal and circular, the mosque, the basilica and the temple, were all mingled with boldness and disregard of convention, but with a result that justified the daring. As Grüner says, "The influence of Byzantine art is clearly perceptible in the variety of colour which is employed, yellow and white and

red and green and black tiles and bricks being used alternately with the utmost skill and the greatest variety of effect."

And now for my suggestion. It is in few words that in face of the present atrophy of British architecture we should go and do likewise, adopting eclecticism in the same spirit as the great art nations above referred to, who, having found a suitable basis to work upon, created national architectural styles answering all their social requirements for centuries. Why should modern English architects be longer satisfied to go on copying, with antiquarian exactness and zeal, structures which are themselves debased imitations of Renaissance buildings, when noble ancient edifices exist in their own dominions only awaiting their application of the eclectic spirit to reward them with the honour, glory and substantial rewards for establishing a new national style of architecture characteristic of their country's world-wide realm?

Considering that the population of India is ten times that of Great Britain, that thousands of Englishmen now visit the country every year, what, Sir, should appear more natural than for Oriental domes and minarets, with their beautiful tracery and variety of everlasting colour decoration, to make their appearance on the horizon of this metropolis of the modern rulers of the great peninsula? A living architect, indeed, has proved that the style can be applied satisfactorily to modern requirements.

HERMES.

Shoreditch Technical Exhibition

SIR,—The Shoreditch Vestry have just established a municipal technical trade school for the woodwork industries, in which 16,000 artisans are engaged in the parish. The school is the first municipal one of the kind in London, and to mark the opening of it an exhibition of antique wood-carving and furniture, with carefully-selected examples of the best modern work of the locality, has been arranged to be held in the Shoreditch Town Hall from May 5 to 13, and to be opened by the Lord Mayor of London, the president of the school.

The antique work will be arranged in historical sequence and explained to groups of visitors by expert demonstrators, so as to make it of educational and artistic value to artisans. Several leading connoisseurs have already promised loans, but to make this section of historical value a large variety of examples of different periods and styles is required. As this is the first exhibition ever held in Shoreditch, whose artisans are practically shut out from the art treasure houses of the West End, will you allow me through your columns to appeal to generous collectors of old carving and furniture to lend a few exhibits for this exhibition, which is intended solely for the artistic education of workers in the wood industries? The fact that some of the technical classes are already in a fortnight filled up shows, I think, that the apprentices and artisans here are alive to the value of technical education, and that they will fully appreciate an artistic exhibition in their midst.—I am, Sir, your obedient servant,

H. MANSFIELD ROBINSON, Hon. Sec. to the Exhibition.

Competition Trickery.

SIR,—Seeing in one of the professional journals an intimation of hospitals being required by the Lanark County Council, we wrote the secretary asking "full particulars," and received some in a few days, but not finding therein any reference to the employment of the successful competitor, we wrote again and put the following plain question: "Will the first-prize man, if known, be appointed architect for the hospitals on the usual English terms?" and received the following reply: "In all probability, if the successful competitor is a capable man, he will be entrusted to carry out the work," which coming, as we thought, from gentlemen of a county council, who would not descend to the giving of a mere tricky reply to so plain a question, we prepared plans on the understanding thus given. In due time we forwarded plans of one hospital to cost 20,000*l.* to 30,000*l.*, and another of smaller size, and were informed officially that we had taken first premium for the large and the second for the smaller hospital, but coupled with this intimation came the extraordinary question as to whether we would undertake all the duties required, plans, specifications, quantities, measuring-up, attendance on committee, &c., for 3 per cent., on which we at once called attention to the plain question and answer sent us prior to the competition and asked an interview.

Instead of an interview, the clerk sent us a printed document headed "To Architects," in which it was stipulated that the premiated plans became the property of the committee, but which document being withheld from us when we wrote for full particulars, and not seen by us until after our plans had been actually accepted, could not with any fairness be considered as binding upon us, and we again asked an interview with the committee, offering also as a compromise to accept the terms recognised in the neighbouring city of Glasgow, although unknown to us. Finally we were asked to meet the committee, and on

Good Friday, of all other days, did so, but only to find that whilst they disagreed amongst themselves as to what the 3 per cent. was to include, its acceptance at all cost was determined upon, and instead of allowing us to read the correspondence (which was but short), and take up the points *seriatim*, we were met by cries of "Yes or No," "We can't sit here all day," and such like; when, seeing the difficulty of getting arguments considered at such a meeting, we promised, in the light of the information then given us, to reconsider the matter and write again in a few days, but from a letter sent us bearing the same date it is evident they no sooner got our backs turned than they passed a resolution withdrawing even the 3 per cent. offered, and a cheque has been sent us for the premiums, showing the intention to keep our drawings and leave us with a paltry 70*l.* instead of the employment we were led to expect on English terms, which would have brought us some 1,500*l.* or thereabout.

Such is the treatment meted out by a county council to an old-established firm of architects, who only competed after careful inquiry as to terms, and whose only fault is that they believed they reply to their queries to be such as gentlemen of a county council would be expected to give and not the mere evasion it has turned out, and to be taken advantage of when opportunity served.

With this publicity we leave the matter for the present, and much mistake our fellow-architects and the journals which so ably represent our profession if such a disreputable transaction is allowed to pass without the most indignant protests.

Yours &c.,

C. O. ELLISON & SON.

Liverpool.

GENERAL.

Excavations are in progress in the caves at Lavant, Chichester, under the direction of Mr. C. Dawson, F.G.S., and Mr. G. Lewis, C.E., and it is expected that the results will add to the knowledge of prehistoric life.

A Chapel of Ease is to be erected in Worthing at a cost of 3,230*l.*

The Brighton Town Council are negotiating for the purchase of property in the rear of the School of Science and Art to obtain a site for the contemplated technical school.

A Board School is about to be erected at Polegate, Hailsham, Sussex, according to plans by Mr. Mitchell, architect.

Mr. W. S. Braithwaite has been appointed architect to the Leeds School Board at a salary at the rate of 200*l.* per annum, with permission to take private practice, the engagement to be terminable by three months' notice on either side.

The Earl of Carlisle has presented to Tullie House, Carlisle, a replica of the bas-relief of the battle of Flodden Field, by Mr. E. Burne-Jones and the late Sir Edgar Boehm.

Mr. R. H. Carpenter, who so faithfully adhered to the practice of his father, the late R. C. Carpenter, in church work, died on Wednesday in his fifty-second year.

The Aberdeen University Court have received a letter from Mr. Charles Mitchell, of the Elswick Works, Newcastle, announcing a further donation of 7,000*l.* towards the extension and improvement of the Marischal College. The total of Mr. Mitchell's donations now amounts to 20,000*l.*

The Governors of Dulwich College have arranged that the Dulwich Picture Gallery will be open on Sunday afternoons from two o'clock to five during the summer months.

The Edinburgh Architectural Association will tomorrow pay a visit to Leuchars Church, and after that will inspect Earlsall.

The Dundee Institute of Architecture met on Thursday evening, the 20th inst., when Mr. Frank W. Young gave a lecture on "The Influence of Minute Quantities of Impurities on the Properties of some of the Useful Metals."

Mr. Lewis F. Day will on Monday evening, the 24th inst., deliver the third of the series of Cantor lectures on "Some Masters of Ornament," in which he will treat of the latter Renaissance.

The Surveyors' Institution meets on Monday, the 24th inst., when the adjourned discussion on the paper, read by Mr. T. Bright at the last meeting, on "Underwoods, their Growth and Utilisation," will be resumed; and, time permitting, a paper will be read by Mr. R. F. Grantham on "Recent Experience in Sewage Filtration considered in relation to River Pollution."

The Annual Dinner of the Surveyors' Institution will take place at the Holborn Restaurant (Venetian Room) on Wednesday, May 31, at half-past six o'clock, instead of the day previously announced.

London and Lancashire Fire Insurance Company.—The directors announce that they propose to pay the same dividend as for last year, viz. 7*s.* per share, free of income-tax, which, with the interim dividend of 3*s.* already paid, makes a total of 10*s.* per share, or 20 per cent. on the paid-up capital, thus absorbing 42,550*l.*

The Architect.

THE WEEK.

ALTHOUGH a manager of Drury Lane Theatre discovered by experience that "SHAKESPEARE" might be taken as meaning bankruptcy, there can be no doubt that the poet's name is every year becoming of more significance to the world. When it is found that for the year ending March 31 no less than 23,966 people went on a pilgrimage to the poet's house in Stratford-on-Avon, and that only about one-half, or 12,381, were Britons, is it not plain that the plays are more and more esteemed as a part of what the Germans call "Weltliteratur"? Ten years ago it was considered remarkable that 12,400 people visited the house in New Place. The figures may now represent the number of foreign pilgrims. The extent to which the whole world becomes kin by the poet's touches is evident when we find that two votaries of SHAKESPEARE came to Stratford-on-Avon from Arabia, nine from Turkey, ten from Ceylon, and five from Japan. It was fortunate for the town that the Yankee showman was not able to carry off the old house, and put wheels under it in order that it might be hawked from State to State in America.

ACCORDING to the agreement just entered into with the Chichester City Council, Mr. BALDWIN LATHAM, C.E., is to receive a commission of 5 per cent. upon the estimated cost of the drainage works (exclusive of the cost of land) set forth in his estimate of November last, and a like commission upon any supplementary expenditure which may be sanctioned. In addition, he will be paid 310% for his charges and expenses in carrying out tidal observations, 145% for surveying work, 50% for Parliamentary work in connection with the preparation and lithographing of plans, &c., and 100% in respect of his time and expenses in attending Government inquiries. Mr. LATHAM may by himself, or by the appointment of a qualified quantity surveyor, or conjointly with a qualified quantity surveyor, in addition to his other remuneration, receive the usual commission of 1½ per cent. from the contractors for the supply of quantities, together with the cost of printing same, and other documents required for the purpose of entering into a contract. The commission will include travelling and other incidental expenses. As to the time of payment of commission, the agreement stipulates that one-half the said commission of 5 per cent. is to be paid to Mr. LATHAM within two months of the sanction being given to the works by the Local Government Board, or the money can be borrowed for execution of works, and in case the works are so sanctioned and the Corporation proceed to carry out the same, then the remaining half of such commission of 5 per cent. shall become due and payable to Mr. LATHAM each month as the works proceed on the amount certified by him to be due to the contractors, and the final balance shall be paid within three months after the works have been completed and handed over to the Corporation, and after the contractor's period of maintenance shall have expired. In the event of the sanction of the Local Government Board not being obtained to Mr. LATHAM's present scheme and another scheme being prepared, then he shall be paid half of the first instalment of 2½ per cent. (namely, 1¼ per cent.) in addition to the sums due to him; and in the event of no further scheme being sanctioned within two years from the date hereof, then a further commission of 1¼ per cent. shall be accepted by the engineer in full satisfaction for his services of every description, and shall be paid within six months after the expiration of the two years. Mr. BALDWIN LATHAM has been asked to furnish the plans, estimates, &c., with as little delay as possible, as it is desired to obtain the sanction of the Local Government Board and to commence operations.

THE London School Board lately attempted to act unfairly towards their quantity surveyors. About a month ago it was resolved, "That in future the provisional sums included in the contracts for new schools, enlargements, &c., be calculated by the architect instead of by the quan-

tity surveyors; that a separate amount for the provisions be specified in the resolution of the Board for the acceptance of the tender, and that the quantity surveyors' commission be calculated on the amount of the tender exclusive of the provisions." It should be remembered that recently the Board obtained tenders from the surveyors which were below the ordinary percentage, as it was understood that allowance should be made on provisions. The surveyors therefore remonstrated. They said:—"In face of the agreement entered into between the Board and ourselves, we submit that no alteration in the terms of the agreement should be made by either party thereto without previous consultation and arrangement. The resolution materially alters the conditions under which the surveyors nominated by your Board contracted to prepare quantities, by taking the provisional sums out of the contract, and thereby depriving the surveyors of their commission upon the most profitable part of their work. The terms of the contract between the Board and ourselves, even before this alteration, were such as to leave only a bare remuneration for professional services." There could be no escape from the argument of the surveyors, and it is therefore proposed to rescind a resolution which undoubtedly was a piece of sharp practice unworthy of a public body, although introduced as an economical stroke.

A REPORT has been presented to the Secretary of State for War by the Council of the Society of Antiquaries of Scotland respecting the condition of Stirling Castle. The parts noticed are the old hall, the royal lodging or palace and the chapel. The hall is said to have been erected by JAMES III., and is 125 feet long by 36 feet wide. It corresponds in general plan with English halls of the same period. It has an oriel or projecting window on the east and west sides of the south end of the hall, and the remains of the stone vaulting are still to be seen. The old roof was removed in 1797, when the whole building was cut up into barrack-rooms, and every architectural feature more or less interfered with. The conversion of this building into a barrack has brought about the destruction of much that must have been interesting. The roof of the building has been renewed, and the officers' mess is now located in it. Originally there were apartments above the state rooms. For the baptism of Prince HENRY, JAMES VI. determined to hold a great function, and Stirling was decided on as the proper place for it. As the existing chapel was too small and ruinous, he caused it to be razed to the ground and a new chapel erected, which is the one now existing. Parliament granted 100,000% Scots for the work, and it was built by a great body of skilled workmen, King JAMES superintending its progress. The ceiling and walls were richly decorated with painting and sculpture. The walls and architectural features are quite entire, but the roof is modern. It is now divided up and used as a storehouse. There is evidently a vault below it, or at least the east end of it. The ground falls rapidly from west to east, and a built-up door exists in the east gable. What most impressed the committee, after an examination of these buildings, was the ruthless manner in which they had been treated to suit temporary purposes, in utter disregard of their historical or architectural interest, and the trumpery character of the new work. Yet they are not so far destroyed but that they might be restored to something of their former condition, were the military authorities willing to give up using them. Mr. CAMPBELL BANNERMAN has informed the Council that with the aid of military advisers he has come to the conclusion that any disfigurement which may have been perpetrated, for the most part at a remote time, cannot be corrected without such changes as would modernise the buildings according to the fancy of some living architect. It is thought better, therefore, to leave them alone, care being taken to keep the exteriors, and especially the decorative work, in good repair, to guard, as far as possible, against decay, and when repairs are executed, to see that they are in the hands of some competent person. The Secretary of State for War is not prepared to go further, as a diversion of the buildings from their present use as barracks would involve the expenditure of a very large sum of money in re-providing accommodation for the garrison elsewhere, apart from the expenses of restoration.

ARCHITECTURE AT THE ROYAL ACADEMY.

THE exhibition of the Royal Academy, which opens on Monday, will not be disappointing to visitors. Among the paintings and sculpture are more pleasing works than were visible last year. The few who will be adventurous enough to invade the solitude of the Architectural Room can also find there very much which will afford enjoyment. This year some consideration has been shown for amateurs. In the majority of cases where several drawings by one architect or firm are accepted they are hung together, and hence it is possible for the public to discover that there is less monotony in treatment than many suppose. Designs by various architects for the same work, such as the South Kensington Museum, the Glasgow Art Galleries, the Oxford Town Hall, &c., can also be contrasted from their positions, and in that way something is done to diminish the difficulties which oppress so many of the public when they attempt to realise the value of modern architecture. Whether the care taken in the arrangement will be appreciated remains to be seen.

Many of the architects whose designs were declined will be sure to cast longing eyes on the blank space that is visible. On the principal wall there are on an average not more than three rows of drawings. It is a convenience to the few who are bound to study the contents of the room when drawings are not hung up to the cornice, but architects, as a rule, are satisfied to have gained admission for their drawings, and are less anxious about the positions in which they appear. The large designs for decoration which are shown in the room will probably be more acceptable to the public than the views of buildings, but no doubt there will be some grumbling about the space assigned to them.

As in recent exhibitions, the absence of public or governmental works is enough to amaze a foreigner, and forms one of the peculiarities of the room to those who have seen the architectural displays of the Continent. The nearest approach to a work of the class is perhaps the Imperial Institute. Mr. COLLCUTT contributes a view of the staircase, in which he proves that it is possible to avoid monotony and to produce an effective whole by depending solely on architectural details, without aid from the sculptor. Competitions follow so fast in this country, the three designs for the completion of the South Kensington Museum by Mr. EMERSON, Mr. T. MANLY DEANE and Mr. W. YOUNG, may appear to architects like ancient history. But they are worth the attention of the public, for they will suggest the risks which attend Government work in this country. It may not be generally known that the preparation of these and other designs was wasted labour, since there was no money available for the work. The cause is commonly attributed to the change of Government, but in reality it arose out of departmental jealousy.

If State works are absent we see enough evidence of what can be done by municipalities. There are three of the five premiated designs for the Oxford Town Hall. It is not difficult to perceive that in the contest between Mr. HARE and Mr. RÜNTZ, the latter must have suffered through his efforts after originality. At first sight there is less symmetry apparent in the second design, and it would be supposed that in consequence there would be less economy of execution. In both there is surface ornamentation, but in the accepted design it is commonplace, and therefore no doubt it was held to be cheaper. The two designs are worth the consideration of young competitors, because they denote how valuable is tact when dealing with municipalities. Messrs. CHESTON & PERKINS's design was probably considered to want solidity from the extent of the fenestration. The design for the County Council House, Stafford, by Mr. W. A. PITE, appears to be too quiet an example of eighteenth-century style to satisfy local rulers. Mr. E. W. MOUNTFORD sends the south-west angle of his Sheffield Town Hall; but as the uninitiated cannot judge of fragments it is likely to be said that, in the building, chimneys and gables are in excess. In the Battersea Town Hall Mr. MOUNTFORD has ably treated a difficult site. The principal front, with its rusticated quoins, capacious semicircular porch and round-headed windows, is stately and substantial, while the side (which stands on an incline), with its ingenious buttresses and massing of the

parts, may be said to be picturesque. The design for Edinburgh Municipal Buildings, by Mr. STATHAM, was also for a site that was not level, and the author's aim was apparently to suggest that the municipal offices would be a guardian fortress for the Old Town and the New. Mr. W. HARRISON's first premiated design for St. Pancras Municipal Buildings shows a building that has dignity and no trace of the fussiness which so often marks competitive work. There is a good porch, a range of round-headed windows on ground floor, a second storey that might be taken as mezzanine, and a third with large square-headed windows, which is evidently the most important. The whole is well combined, and there is nothing to which economical reformers in the parish can take objection. Mr. W. M. FAWCETT's Cambridge Guildhall is also of the cubical block type, but more Classic in expression. The first storey is adorned with pilasters, and they do not appear out of place by contrast with any of the other parts. Messrs. BRADSHAW & GASS have selected English Renaissance for the Town Hall and Offices, Farnworth, and have treated it effectively. The Police Offices, Birmingham, by Messrs. A. WEBB & INGRESS BELL, is a very important example of a public building for a town in which it was requisite to be sparing of expense. The proportions being satisfactory the severity does not appear misplaced. If the Victoria Courts could also be shown the value of the work would be heightened by contrast. Mr. C. F. HAYWARD's Local Offices and Fire Station at Harrow is rather small in scale, and the necessity of having a fire-bell is turned to good account, as it gives opportunity for the introduction of some telling wrought-iron work; but the real crux of such a building is evaded, since there is no provision for sheltering a fire-escape. The fine drawing of FORMENTONE's Town Hall, in Brescia, by Mr. J. C. WATT (this year there are very few examples of ancient work) should not be overlooked in examining the municipal buildings.

The importance which is attached to provision for education is apparent. The Municipal Technical School, Manchester, by Messrs. SPALDING & CROSS, may well be described as palatial. The departments are indicated, the size of the windows will enable any light that forces its way through the smoke to be used, and the numerous gables will enable the building to assert itself on dull days. It is creditable to Manchester to erect such a building, and yet the outlay is a wise investment. The Northampton Technical School, Clerkenwell, is the subject of designs by Messrs. ROGER SMITH & SON, who believe in the virtues of capacious windows. Mr. E. W. MOUNTFORD, in his design for the same building, introduces much variety of grouping as in his other works. His St. Olave's Grammar School is a good example of its class. In the Leeds School of Medicine Mr. W. H. THORP was apparently desirous to impart a sort of domestic character to the building, which would gratify students, and to suggest the professorate by a tower. The combination is more agreeable than would be afforded by a severe Classic style. The Glasgow Art Galleries may be included with the educational buildings. The accepted design by Messrs. SIMPSON & ALLEN will explain the controversy that arose in the north when it was accepted. The amount of ornamentation in statuary and relief, and the variety of the parts, at the first glance suggest a costly design, but the effect is undoubtedly attractive, and if the building can be carried out as here represented it will look well on the site. Messrs. MORRIS & HUNTER adopted a more severe treatment, but one that is not uncited to Glasgow. There is more power of composition in Mr. T. MANLY DEANE's design, which should discredit those who maintain that only Scotsmen can manipulate northern details; but probably it was considered too massive for a building that was to be a resort for pleasure-seekers. In his new British Gallery, Millbank, Mr. S. R. J. SMITH, we suppose, wished to suggest a relationship between the building and the National Gallery. There was not much difficulty in surpassing the obnoxious "pepper castors" by transforming them into graceful domes. The style adopted is Classic, and visitors will be grateful when they find that so large a part of the galleries consists of only one floor, which will be lighted from above. Mr. KOCH has a Board school at Gais, Switzerland, which somewhat resembles the ordinary London Board school, with the exception that the windows

are smaller, and there is consequently more solidity. The Public Library, Colchester, by Mr. B. BINYON, is of red brick, with a very large window in the middle. Mr. J. M. BRYDON'S Village Hall, Forest Row, is of the cottage type. The School of Needlework, South Kensington, by Mr. FAIRFAX WADE, is so quiet as to be remarkable amidst so much that is pretentious in the region.

(To be continued.)

MUNICH.

BY A CORRESPONDENT.

IT will commonly be found that visitors to Munich, especially English visitors, display more or less uncertainty when they are criticising the city. They treat it as a sort of puzzle. Most of the greater towns of Germany are sure to surprise the stranger, for where he expected antiquity he is likely to find an imitation of something that was to be found in Paris not earlier than the eighteenth century. The princes who went to pay their respects to LOUIS XIV., if they did not bring back French gold or a promise of it, carried home a belief that to become every inch a king it was necessary to dwell in a building that was an imitation of Versailles. Reverential subjects imitated their highnesses on a becoming scale. Now in Munich one sees evidence enough of the influence of France on the buildings; but that is not all. You have exotics of many other sorts. If you are disposed to dream as you perambulate streets at home or abroad you may in Munich be suddenly transported to Florence, and you will scarcely have discovered you are the victim of an illusion, and that you are standing in the Bavarian capital, than you are likely to imagine, after taking a few steps, that you must be in Rome or Milan, in Athens or Ravenna. You have spent, say, an hour in the Basilica of St. Boniface, and may be endeavouring to determine for yourself, after seeing an artisan's marriage in it or a christening, whether a costly copy of St. Paul-without-the-Walls is an ideal modern church, when you find yourself in front of the neighbouring national Palace of Glass. Here, at least, Munich designers should be free; but if you are unable to recall the exhibition building which served as the prototype, you are convinced that you have seen engravings of it years ago. Then the notion, in spite of its absurdity, may arise within you that Munich is only a scattered Sydenham, or that Sydenham is a compressed Munich.

While one is in so hesitating a mood it is astonishing how interesting will become the comparatively few buildings that have survived the mutations of kingly and electoral taste in Munich. The Frauen-Kirche dates only from 1468, and is therefore not of the purest type of Gothic. An English critic in the early part of the century condemned the exterior as "frightful in the extreme," and in the interior the air and dust of four centuries appear to have been preserved. But after a general survey of the streets of Munich the student of architecture will find that he prefers to go round and round the church to while away time rather than to renew acquaintance with what is outside. He may have admired the cast of the monument of LOUIS IV. in London, but in the Frauen-Kirche it assumes a new interest because it is genuine. In any other city the church of St. Cajetan would be condemned as an example of the ultra Rococo; in Munich there is relief in the extravagances, because they appear more human in their fallibility than the chilling correctness which is visible in so many of this century's buildings.

A judge of the MATTHEW ARNOLD type would, however, find much to gratify him in Munich, for if the function of criticism is to rule all things, to hold sway especially over all men who claim to be artists, there is no doubt it has had a better opportunity to show its strength in the Bavarian capital than in any other city, ancient or modern. There is scarcely a street which does not present something to testify how inferior is the individual artist if valued beside some formulation of a principle. The critical spirit had demonstrated about sixty years ago what was proper to be done in the way of building, and ever since the architects have been trying to realise the discoveries which the æstheticians had drawn out of their studies as amateurs.

Fate was undoubtedly favourable to all those in Munich who had faith in "the bookish theoretic." In 1825 LOUIS, who

was the second king of Bavaria, reached the throne. He was an enthusiast for whatever was Greek, even in name, and for a long time he was a yearly visitor to Athens. In 1829 he published a volume of verses, but he had not much belief in the inspiration of his contemporaries. He considered his subjects would be better employed in imitation of ancient works than in setting up freaks of their own, and in order to convince them he decided that Munich should exemplify what His Majesty considered was the best work that had been produced by Greek, Roman, Mediæval and Renaissance hands. If LOUIS were as strong as NAPOLEON, who was the creator of the kingdom of Bavaria, he would have carried off every stone of the buildings he admired, and have set them up again triumphantly in his capital. The King's limitations, however, became a source of new pleasure. LOUIS was able not only to erect imitations of the buildings he admired, and as they appeared when most perfect, but he could also have them adorned with paintings and sculpture that would gratify his own inclinations, and correspond with the theories of the Court philosophers. In that way Munich would present an appearance still more unlike what was to be seen in Nuremberg or Innsbruck, and more becoming the capital of so important a kingdom. The king's family are still visionaries, and LOUIS may have imagined that he was doing much to make his country a connecting-link with Italy, Rome and Greece in the chain of civilisation. One of his unhappy successors, it is well known, wished to renew the connection with the France of the Willkürregiment that had passed away with the POMPADOURS and DU BARRYS, as well as with the far more remote mythic period of the Wagnerian "Gottterdammerung;" but, failing, he sought relief under the waters which he loved to traverse as the Knight of the Swan. Apparently it was not believed at Court that Bavaria could stand alone or work out an independent destiny.

King LOUIS could not have discovered a more suitable architect than LEO VON KLENZE. He had mastered Classic and Renaissance styles, and he was willing to evince his reverence for them by combining them in a manner that would be considered illegal if ordered by an inferior architect. He began with the Königsbau, which would recall the Pitti of Florence if it were not for the Doric entablature of the lower storey and the Corinthian and Roman pilasters in the upper storeys. The palace seems absurdly strong for a city in which the inhabitants are loyal. In the interior the architect meekly sacrificed a reputation for planning in order that ample room and verge enough should be provided for the series of paintings by SCHNORR, KAULBACH, ZIMMERMANN, friezes by SCHWANTHALER, and other decorations. The pictorial work is undoubtedly remarkable. No artist could work on so large a scale and so correctly who had not mastered all the knowledge that was attainable in a German academy. But as often happens with learned artists, the draughtsmanship is superior to the colouring. In spite of what GOETHE had written in his "Farbenlehre" (and the English scientists who profess to have demolished his conclusions would do well to remember that during forty years Professor HELMHOLTZ championed them), it was not possible sixty years ago to convince German artists of the importance of the relation between colour and form. They were taught so much about figure, how "der Künstler gibt Bilder" and "Bilder nehmen die Sinne auf," and so on, they concluded that mental images were comparable to cartoons in black chalk, which might vary in definiteness and beauty, but were colourless, because colour was unnecessary to their significance and appreciation. To people who were brought up on German metaphysics, the paintings of subjects derived from the "Iliad," the Greek tragedians, the histories of CHARLEMAGNE, BARBAROSSA and RODOLPH of Hapsburg, which are seen on the walls of the Königsbau, would not be made more expressive if a second TITIAN had executed the colouring. They were accepted as examples of the ideal as far as it could be depicted; the compositions were considered, as it were, by the mind's eye of every onlooker, and in that way they were deemed to be satisfactory. Critics whose eyes had grown dim by poring over books, and to whom most things seemed of the colour of printed paper, realised the intentions of the artists, and were indifferent to short-

comings of execution which to a colour-grinder in a Renaissance workshop would appear ridiculous.

It would be unjust for any one to judge of the experiments in painting by the appearance which the pictures present to-day. Time has not dealt more tenderly with the Munich frescoes than with those which are to be seen at Westminster. The external work has suffered, and the writer must admit that he prefers SMIRKE'S Post Office or even WILLIAMS'S at St. Martin's-le-Grand to the Postgebäude in Munich, which forms part of a group with the palace and opera house. Although its polychrome decorations must have been ambitious, they have now as used-up an appearance as if they belonged to the halls of dazzling light in some broken-down Cremorne. Elsewhere in the city the colour work is not more persuasive—at least to English eyes—than the crude plates which are produced for the benefit of students in treatises on polychromy. There is, or rather was, in the Munich paintings a comprehension of the law of contrasts, and the colours are rightly chosen for the positions in which they are laid; law, in fact, is supreme everywhere, and probably nothing was done without a precedent whose existence is duly recorded in an official report, but the difficulty is to find anything which denotes that the painters possessed feelings and were not afraid of experiments which would give them pleasure. Is it disappointment with so much of the coloured architecture in the streets which makes so many of the paintings in the Pinakothek appear almost fascinating? A visitor who sees many galleries may grow sceptical about RUBENS'S power as a colourist, but in Munich he becomes almost refreshing, and one is indifferent whether the numerous dozens of pictures which bear his name contain any of his handiwork. They have at least his characteristic effects, and one's gratitude is excited. Another example may be allowed. PIOTY is prone to exaggeration in his colour experiments, but go straight to his picture, after a contemplation of the frescoes outside the galleries, and you are likely to say the artist must be a man of genius. May it not be said that the important sculptures in the Glyptothek hardly seem to convince every visitor that they once adorned temples and public places in Greece? It is difficult for a moment to resist the misgiving that they also were reproduced, restored or in some way manipulated according to the canons of the local professors.

If those canons were attempts to get at the essence of things they might be excused, as well as any artists who accepted them because they helped to impart consistency to work. But in Munich the initiative for all the speculations about art and the buildings which were raised were derived from the fads of King LOUIS. He believed he had discovered the noblest works, and too many able men were ready to aid in demonstrating the infallibility of the royal perception. It would be absurd for anybody to suppose that it was not possible to excel the work done by machines at any time, and yet it is taken for granted that the human machine declines in power after it has attained some efficiency. Munich presents so much evidence of the latter assumption as to become depressing to everyone who believes that art is not outside the influence of the law of progress. The disappointment which is felt at seeing how valueless are the efforts which once were made to resist that law is, however, a good sign, for it is an expression of a belief that political power should never be allowed to control an art.

EGYPTIAN EXPLORATION.

IN a communication to the *Manchester Guardian* Mr. W. St. C. Boscawen writes:—

In the hills of the Gebel-el-Gebrai, which derive their names from the small Coptic village of Dier-el-Gebrai in the plain, there are a number of tombs of officials who lived during the reign of the Pharaoh Nefor-Ka-Ra-Pepi, or Pepi II., and who were governors of the Nome of Tuf Antaeopolis, and also priests of the pyramid of the king. This office of priest of the pyramid or pyramid temple is one of the oldest in the hierarchy of Egypt. In the tombs at Sheik Said we find the burial-place of a man who was priest of the pyramids of Kufu and Usorkauf, of the Fourth and Fifth Dynasties, and in the museum of Gizeh there is the inscription of an official, Tepe-Ankh, who was priest of six pyramids, including those of Kufu, Kephren and Menkara, and the still older pyramid of Senefru

at Medum. The discovery of these tombs is of special interest as the pyramid of Pepi II. is still unknown. That of Ra-mori Pepi I. was opened at Sakkarah in 1880, but no indication has been afforded as to the site of that of Pepi II. until the discovery of these tombs. Here the name of the pyramid is given as Men-Ankh, "the Support of Life." During the last few months many records of Pepi have been found in this district and in the neighbourhood of Mer, on the west bank of the Nile, where some very fine tombs have recently been opened by the authorities of the Gizeh Museum. In the neighbourhood of Namir, opposite Manfalut, on the borders of the Lybian desert, there are the remains of a pyramid which it is now supposed may be possibly that of Pepi II. The early part of the Sixth Dynasty, about B.C. 3200, was one of the most prosperous periods of the early Egyptian empire and the tombs here amply prove this. The paintings in the tombs, though considerably damaged by the Copts, are among the best in Egypt, and furnish us with almost every detail of the domestic life of the people. The best tomb is that of Jau, whose name and titles are found in an inscription which reads as follows:—

Priest of the pyramid of Nefor-Ka-Ra (Men-Ankh), the Support of Life, Great Chief of the West, Ha Prince, Royal Chancellor, familiar friend of the King; Lector, Superintendent of the South, Great Chief of the Antaeopolite Nome; the devoted one towards the great god the Lord of Heaven, the veteran Jau.

The inscription is beautifully drawn, and is painted in green upon a red ground. The walls of the tomb are covered with paintings representing harvest scenes, fishing scenes, and the usual vocations of the deceased. One of the most lively scenes here is that which represents the dancers who danced at the *Ka* festivals. The girls are perfectly nude, and have their hair done in long plaits which hang down the back. To the end of this plait a ball or inflated bladder is tied, and part of the dance seems to consist in kicking the bladders on each other's heads. On another wall a number of ships are represented, including the funeral bark of the deceased, which exactly resembles the small models of boats so often found in the tombs.

Close to the tomb of Jau is a smaller tomb, terribly mutilated by the Copts, but containing some of the most important paintings that have yet been found. Here we have on the walls a complete series of little tableaux representing every trade, profession or domestic service known in Egypt, and, what is more important, every group is accompanied by a hieroglyphic inscription giving the explanation of the picture. We learn from this remarkable painting not only the different trades but the names of the trades, and in many cases the names of the different processes in the work. Here we see the sculptor cutting out of stone the funeral or *Ka* statue of the deceased; in another group the painter painting it; the wood carver makes the coffin and paints it, and smaller wooden statues; while another carves the staff of divine strength to place in the hand. In another group the carpenters make furniture; cabinets, chairs, tables are being neatly made and polished. The most interesting series of pictures are those illustrating the working of gold. We see the whole process: washing the alluvial in a cloth cradle, gathering the dust, melting it with the blow-pipe, casting into ingots and weighing the final result—each of these processes is most fully described, and the whole forms one of the earliest chapters in the history of mining. So also every process of ship and boat-building is figured and described. For domestic service there are scenes illustrating the work of the baker, butcher, butler, the weaver and many other domestic occupations. The official in whose tomb these paintings were found is named Apa; he was also a governor of the Nome and a magistrate, and upon these walls his judicial functions are recorded. A crime has been committed; we see the police in search of the criminal and arresting him by seizing him by the head. He is brought before the judge, and we next see him being bastinadoed. These tombs are now being copied by the members of the Archaeological Survey of Egypt, under Mr. Newberry, and their publication will add much to our knowledge of the life of Egypt in the thirty-third century before our era.

In another letter Mr. Boscawen says:—

On the east bank of the Nile, about 170 miles from Cairo, there rise almost perpendicularly from the narrow fringe of verdure a row of limestone cliffs, perforated with openings, the entrances of tombs. The line of hills is known as the Gebel-beni-Hassan, and is the site of the necropolis of the ancient city of Menat Khufu, the "nursing city of King Cheops," the builder of the Great Pyramid. It is difficult to explain exactly the meaning of this title, the "nursing city of Khufu," but it seems to have been one confined to the days of the early empire, as it is also found in the name "Menat Senefru," the "nursing town of Senefru," found by Dr. Flinders Petrie in one of the tombs near the pyramid of Senefru at Medum. Although the town of Menat Khufu belonged to the pyramid age, the tombs here do not represent burials of that period, but of the later age of the Twelfth Dynasty: that is, about twelve

centuries later. They belong, indeed, to the most important and glorious period of the Egyptian empire, when the pure Egyptian civilisation, uninfluenced by foreign intercourse, had reached its highest development. There are in the hill thirty-nine tombs arranged in two groups, and of these twelve are inscribed and painted. The inscriptions in the large tombs, especially that of Khnumhotep II., give us a wonderful insight into the life and social customs of the age, which are still further illustrated by the beautiful paintings with which the walls are adorned. In some of the tombs dates occur, and thus we are able to fix with accuracy the period when they were executed. They range between the age of Amenemhat I. and Usertesen II., of the Twelfth Dynasty, and therefore about B.C. 2400-2300, one of the most interesting periods in Oriental history.

To the ancient Egyptian the making of his tomb, or "eternal house," was the great duty of his life, and hence the magnificence of many of the tombs here. The truth of this is confirmed by the following passage in the inscription of Khnumhotep, who places clearly before us the reason for building his tomb:—"My first honour," he says, "was in establishing for myself a tomb-chapel. For a man should imitate the acts of his father. Now, my father made for himself a *Ka* house in the city of Mernefer, of good limestone, that he might establish his name to eternity." He also gives us another reason for the construction of this tomb, which throws much light upon the feudal character of the life of the time:—"He made this tomb as his monument, that it might establish his name to eternity and make it endure for ever;" and then he says, "that he might establish the name of his staff, arranged according to their rank, his household officers, whom he promoted from being serfs." This association of master and servant in life and death is a curious characteristic of the life of the early Egyptian empire, and is no doubt a survival of the older custom, when the slaves were slain at their master's tomb to accompany him and tend him on his long journey. It will be seen at once how important this custom is in restoring to us the life of the period. Not only do we obtain the names and titles of the deceased from their tombs, but also the names of their wives, sons, daughters and servants, from the highest steward of the household down to the donkey-boy. And when we bear in mind that each of these names accompanies a portrait, we have an increased insight into the life and surroundings of the deceased.

The feudal character of the age is still further borne out by the statements of the duties of a governor found in the tomb of Amenai, or Amenemha, who, after a period of office of twenty-five years, died in the forty-third year of the reign of Usertesen I. "I cultivated," he says, "the entire nome (Oryx-mone) with many workpeople. I troubled no child, I oppressed no widow, neither did I keep a fisherman from his fishing, or a herdsman from his herd. There was no head of a village whose people I had taken away for compulsory labour (*corvée*), and there was no one unhappy in my days or hungry in my times. When a famine arose I tilled all the fields in the nome, from its south to its northern boundary, and gave nourishment and life to its inhabitants. To the widow I allowed as much as to the wife of a man. When the Nile rose again and everything flourished, fields, trees and all things, I cut off nothing from the fields." This interesting passage may be compared with the famous inscription of Baba at El Kab, which records a famine, as well as the curious record of a seven years' famine on the Stela of Sheshef of King Teser, all of which show that droughts due to low Nile did then occur, producing famine and want. In such time it was the duty of the governor of the nome, who stood *in loco parentis* to his people, to provide relief. The plans of the tombs of the princes at Beni-Hassan are mostly on the same plan, but that of Khnumhotep II. will best illustrate the architecture of the period. The entrance is by a "portico in antis." The shafts are of the Proto-Doric type, sixteen-sided and resting on circular bases. The height of the portico is about 18 feet, with a depth of 10 feet, and affords access by a doorway to a large chamber. This chamber, the guest or *Ka* chamber of the tomb, is a magnificent room, being 31 feet long by 30 feet broad and 18 feet high, the roof being supported by four massive sixteen-sided columns slightly fluted, and in the floor are the openings of two large mummy pits. Opening out of the east wall is the shrine, in which were the statues of the deceased. The chamber is about 8 feet by 10, and beautifully painted, but the statues have been quite destroyed. The main chamber, in which the guests were received on festival days, is one mass of painting, illustrating every detail of the life of the deceased and of the Egyptian life of four thousand years ago. Here we see almost every detail of the daily life, similar to those we are familiar with in the tombs of the early empire, such as the tomb of Tii at Sakkarah. Carpenters and ship-builders are at work making the sacred boat or ark to carry the body of the deceased to Abydos, to rest by the side of the tomb of Osiris, and after a time to return to his own resting-place here in his native place. Potters are making vases of beautiful

shape, and women are baking bread for the everlasting journey, whilst all the work is being inspected by the master, carried in his litter. It is impossible to describe in detail all the beauty of the work here; but here we see the great man engaged in fowling on the papyrus marshes on the banks of the Nile, a sport—together with fishing, which is also represented—of which the Egyptians were particularly fond. Here we see Khnumhotep in his boat, hunting birds and armed with a fowling-stick or boomerang. He is accompanied by his wife, the lady Kheti, who is described in the inscription above her:—"The daughter of an Ha prince, the lady of the house Kheti, his wife, his beloved one, the priestess of Hathor," while in front of the boat is the body servant or valet; Khnumhotep, holding his sandals. The beautiful part of the work is the colouring of the birds and the flowers. Here we have the ibis chasing a butterfly, cranes and other birds, while in the reeds are kingfishers, their nests being shown. Among the birds are weasels, which are frightening them from their nests. The painting of every feather, of each spot on the butterflies is most accurate, and at once suggests attention to the only art of Christian times that approaches it, namely, that of the Japanese. In Egypt, as in the far Eastern kingdom, there was an intense love of nature coupled with a great artistic skill and patience. In Egypt the artist, with his palette of seven fine colours and his brush of a frayed reed, produced these wonderful representations of nature, because of his inborn artistic skill, and like the Jap, his intense love and study of nature. The Egyptians in their simpler days, when the civilisation was not spoiled by foreign contact, were very like the people of Japan, intensely conservative, living within themselves, with a simple almost patriarchal feudal system of government—happy and childlike in their family relationships, husband, wife and children, master and servant, all being bound by a sort of friendship and, above all, an intense love of the beautiful in nature.

In this age we have the "Age of Flowers." The husband garlands his wife with flowers, and she him; guests at the feast are crowned with flowers, and the altars of the temples are heaped with brilliant blossoms. To this age belong the "Love Songs" translated by Maspero, which so closely resemble the "Song of Solomon" and the amorous poem of the "Garden of Flowers." This trait survived until a long time after, and, indeed, never died out entirely. In the Amen-am-hib at Thebis, of the Eighteenth Dynasty, we have the resting-place of one who was a great lover of flowers. Here at the banquet his wife has a green lotus-bud in her hand, and all the ladies have crowns of flowers and lotus-buds in their hands, while in another scene we have the garden of the great man represented full of flowers. Khnumhotep had his gardens, and the names of his gardeners are preserved to us, and may be those of the oldest in the world—Neferhotep, Neter-nekht and Hotep. Such are only some of the features of this beautiful tomb. For such a magnificent resting-place there must have been an artist designer, and fortunately his name is preserved to us, for at the end of this long inscription his writer says, "He who undertook the tomb the director of the works was Bakt." His name deserves to be handed down to posterity as one skilled in the fine arts. The history of the owner of this tomb is given in a long inscription of over two hundred lines of writing in beautifully painted hieroglyphics on the west wall, and reveals to us many points of interest as to the offices and their nature.

DUNDEE INSTITUTE OF ARCHITECTURE.

THE fifth ordinary meeting for the session of the Dundee Institute of Architecture, Science and Art was held last week in the Upper Hall of the Y.M.C.A. Mr. William Mackison, the president, occupied the chair. Mr. Frank W. Young, director of studies in the Technical Institute, delivered a lecture on "The Influence of Minute Quantities of Impurities on the Properties of some of the Useful Metals."

Mr. Young, after a few introductory remarks, said very small quantities of mineral matter in the tissues of plants and animals were now known to be absolutely indispensable for growth and well-being. A small percentage of water vapour in the air was all important, as preventing the rays of the sun from being in our latitude unbearably hot by day, and the earth's surface from becoming excessively cold by night. Recent researches had shown that it was the omnipresent moisture which determined a large number of chemical changes. For a number of years it had been known that dry chlorine would not bleach, and now they were told it did not, in a pure and dry state, act on a number of elements for which it ordinarily exhibited a marked affinity. Anomalous as it appeared to be, there was now very reliable evidence to prove that carbon would not burn in pure dry oxygen, nor would a mixture of pure dry carbonic oxide and oxygen explode without the presence of a little aqueous vapour, which indeed required most unusual precautions for its elimination. Should that kind of research be con-

tinued there was good reason to expect ere long a new chemistry, that of pure and dry substances, and there was good foundation for the opinion that in some important respects the properties of the pure elements would present marked contrasts with our present knowledge. But the task of removing small quantities of foreign substances was a peculiarly heavy one, and the difficulties in the way of lost traces of some of these appeared well-nigh insuperable. Pure elements occurred nowhere in nature. The ores of metals almost invariably consisted of a compound of the metal (oxide, sulphide, carbonate, as the case might be), associated with a number of foreign bodies, often making up a very considerable weight of the material. After instancing this in the case of zinc, lead and copper, Mr. Young remarked that the bodies known as cast-iron, steel and malleable iron had each of them somewhat varying proportions of carbon, silicon, phosphorus and often sulphur and manganese. Malleable iron approached most nearly to the pure condition of that metal. It was now very generally admitted that the carbon present in cast-iron was in two forms: (1) graphitic carbon, and (2) combined carbon, and that the relative amounts of these was in great measure determined by the temperature of the smelting-furnace and the conditions of cooling. As regarded the presence of silicon in iron, it had been customary to speak of it as exercising, in the case of cast-iron at any rate, an influence not greatly dissimilar to that of carbon in diminishing the melting point and hardening the metal. It had been shown that, contrary to prevalent opinion, silicon increased the tensile strength and limit of elasticity, rendering the metal quiet in the mould when cast, and on the whole exerting in suitable proportion a beneficial influence on the properties of cast-iron. The metal manganese was always present in iron and cast steel, but the part which it played had not as yet been very satisfactorily made out. It was believed to soften the metal to some extent, and to render it less fusible, while in puddling iron it appeared to assist in the removal of sulphur and silicon. Willis had shown that a certain variety of steel containing no manganese would break into pieces at the first blow of the hammer, whereas a similar ingot containing 0.8 per cent. of the metal would forge readily. The general effect of sulphur and phosphorus on iron was unfortunately too well known to smelters. Small quantities of sulphur (say from 0.3 to 0.5 per cent.) in iron tended to the production of white cast-iron, while even as small a proportion as .03 of the element would make malleable iron or mild steel brittle and unmanageable at a red heat. Phosphorus increased the fluidity and hardness of cast-iron, while its presence to the extent of 0.5 per cent. or so in wrought-iron or steel ruined these metals by rendering them distinctly brittle at low temperatures. The tenacity, at the same time, was much lessened. Cast-irons invariably contained it in greater or less proportion, and in the making of malleable iron therefrom special care was taken to eliminate that impurity. Mr. Young then proceeded to illustrate the influence of very minute quantities of impurities on gold, zinc, copper, &c., and said the effect, as a rule, was out of all proportion to the amount added. In many cases beneficial, it was often most prejudicial, and the metallurgist made every effort for the removal of the evil. Yet in the case of a number of metals so many foreign bodies were present that it was not always certain which of them, or how many, were of advantage or the reverse. Even in the case of iron the conclusions arrived at were still in some degree problematical. Hence the necessity for combined and systematic research on the part of both the skilled chemist and the mechanic.

EDINBURGH ARCHITECTURAL ASSOCIATION.

THE Edinburgh Architectural Association paid their fifth sessional visit to Leuchars Church and Earlsall, under the leadership of Mr. R. S. Lorimer. Among those present were Mr. Balfour-Paul, Lyon King-at-Arms; Professor Baldwin Brown; Mr. J. M. Gray, National Portrait Gallery, &c. Owing to the courtesy of Mr. R. W. R. Mackenzie, an opportunity was afforded the members of inspecting Earlsall, which is in many ways a unique example of a Scottish mansion of the end of the sixteenth and beginning of the seventeenth centuries. The house had for a period of over seventy years been abandoned, and was fast falling into ruins when it passed a few years ago into the hands of the present proprietor, and has since been restored under the direction of Mr. R. S. Lorimer, architect. Leuchars Church having been first examined, the party passed on to Earlsall, which lies about a mile distant, and they were there received by the proprietor, Mr. R. W. R. Mackenzie. Mr. Lorimer, in his description of the house, mentioned that the first trace to be found of the name of Earlsall was in a charter of James IV., dated March 28, 1497, whereby the king bestowed anew on Sir Alexander Bruce "the lands of Earlsall and Pruck." It was the fifth laird, Sir William, who succeeded about the year 1580, whose name was

associated with the building of Earlsall. The plan of the house, said Mr. Lorimer, is a development of what is called the L plan—that is, two buildings at right angles to each other, with the main staircase in a tower in the internal angle—and in this case there is also a large tower at the north-east corner. In continuation of the western front there is a high enclosing wall connecting the main house with some smaller buildings, the whole forming a courtyard, in which the old draw-well is placed, and enclosed on the east side by a low wall and balustrade, and this side of the courtyard opens directly into the garden. Though not large the house contains several notable rooms, the most interesting of which is the gallery on the second floor, measuring 50 feet by 18 and some 13 feet high, and containing a painted ceiling of very curious design. This is a wooden boarded ceiling taking the form of a flat semi-ellipse, and comes down on to the walls without any cornice or moulding. The upper part of the wall is divided into compartments by arcading formed of painted pilasters and flat arches. In each compartment was a motto. Most of these have long since disappeared, but one of the few remaining informs the reader that "A nice wyf and a back doore oft maketh a riche man poore." The ceiling itself is divided into upwards of 300 panels, alternately square and circular, and joined by scrollwork. The circular panels are filled in with heraldic devices, the arms of Bruce of Earlsall being depicted in the centre. Immediately around are grouped shields bearing the cognisances of the families with which the Bruces were allied matrimonially, and to the west the arms of many of the noble families of Scotland. The square panels are filled in with representations of animals, which, there is little doubt, were copied out of some Mediæval "bestiary," of which examples still exist in the Bodleian at Oxford and elsewhere. The decoration, which is in black and white distemper, is altogether a piece of seventeenth-century fancy-work quite unique in its kind. Its preservation was a task of some difficulty owing to the deplorable condition that the roof of the house had been allowed to get into. The ceiling in a bedroom shows decoration of a similar character. This is a flat ceiling formed of massive beams with plain boarding, the space between the beams being divided into panels by scrollwork, with a picture of an animal in each alternate panel. It is curious, in a house of this date, to find that it does not contain any enriched plasterwork, a form of decoration in which some of the old Fife houses are very rich. The "cat-hole" is to be seen cut through the lower panels of many of the doors. This seems to have been a common custom, and sometimes the hole was provided with a little sliding shutter on the room side of the door, the use of these holes apparently being to enable the cat to hunt the house from attic to basement whenever the humour seized her. The fireplace in the stone hall is also worthy of note, as it has a granite lintel 11 feet by nearly 2 feet deep, and all in the one piece.

ARCHITECTS AND BY-LAWS.

AT the Birmingham County Court, on Saturday, an action brought by Mr. Moses Levenberg, a gentleman residing in London, against Mr. William Wykes, architect, Colmore Row, Birmingham, to recover 50*l.* damages for alleged fraudulent misrepresentation, was tried by his Honour Judge Chalmers and a jury. The case for the plaintiff was that in 1887 he erected three houses, Nos. 21, 23 and 25 Portland Road, Edgbaston. The defendant was employed as the architect and Mr. Brookes as the builder. The specifications drawn up by the defendant showed a separate drain communication from each house with the main sewer by a 6-inch soil-pipe. From time to time Mr. Wykes gave certificates that the work was being carried out, and on these the plaintiff made settlements with the builder. Subsequently Mr. Wykes gave the plaintiff a plan, which showed that the drains had been laid as required by the plan deposited with the authorities. Plaintiff had no reason to think otherwise until November 1892, when he received a letter from the sanitary inspector stating that the drains had not been laid in accordance with the plans deposited with the Corporation. An investigation showed that a 9-inch soil-pipe had been laid from No. 23 to the main, and that the drains from Nos. 21 and 25 communicated with this soil-pipe and not with the main. As a result, the complainant was compelled to alter the drains and spent about 24*l.* in laying them in accordance with the original plans. Plaintiff therefore contended that he was induced, by the defendant giving his certificates to the builder, to pay the builder the money payable under the contract, whereas the drains were not laid in accordance with the contract. Evidence was given by the plaintiff, who admitted in cross-examination that the defendant had power under the contract to make alterations and deviations from the plans.

Mr. Young, on the part of the defence, did not dispute that the work was not carried out according to the plans, or that the plaintiff had to spend money in 1892 to alter them. Defendant

said he was quite aware at the time that alterations were being made in the system of drainage. He sanctioned the deviations, which did not break the by-laws then in existence. He did not think it was necessary to draw the attention of the plaintiff to the deviation when he sent in the account for deviations. He had no intention to deceive, and acted honestly, as he thought, under his power as architect. In cross-examination defendant said he did not inform the Corporation at the time he made the deviation.

The jury found for the plaintiff, with 24*l.* damages.

Mr. Hugo Young applied for a stay of execution on account of misdirection. His Honour had directed the jury that they were entitled to consider whether by the certificates or by conduct the defendant had made a misrepresentation. He submitted that the judge was not justified in making such a direction, as the only fraud alleged in the particulars was the giving of the certificates.

His Honour said the certificates in themselves were nothing—the conduct was in sending the certificates.

Mr. Young said of course he did not know what view he might take as to appealing, on further consideration.

His Honour granted the stay of execution for twenty-one days on the payment of 25*l.* into court.

ARCHITECTURAL CONFERENCE IN LIVERPOOL.

A CONFERENCE of delegates, representing architects in various towns, was held on the 21st inst. at the University College, Liverpool, for the purpose of considering the proposals of the Council of the Royal Institute of British Architects "for dividing the United Kingdom into architectural provinces or districts, of which the societies now or hereafter allied to the Royal Institute would be the respective centres, one object of thus dividing the United Kingdom being the promotion of architectural education by the systematic organisation for educational purposes of such means of instruction as are at present available in the respective centres."

Mr. Henry Hartley, vice-president of the Liverpool Society, was chairman. The delegates came from Manchester, Leeds, Sheffield, Birmingham, Dublin, Liverpool, Nottingham, Bristol and Leicester.

Mr. Solomons moved, "That this conference of delegates from the provincial architectural societies in alliance with the Royal Institute of British Architects has heard with great satisfaction the proposal to divide the United Kingdom into architectural provinces, which, if successfully carried out, will so materially advance the interests of the profession throughout the country." The whole scheme seemed so desirable that he did not anticipate the slightest opposition.

Mr. Culshaw seconded the motion.

Mr. Arthur Cates said they had at present thirteen societies and possibly two or three more might be organised in the south and west. He could not say exactly what was proposed to be done in Ireland, but he thought from fifteen to sixteen would be the number all told.

Mr. T. Drew, R.H.A., said that at present they proposed only one centre for Ireland, at Dublin.

Mr. Beckwith said that there was no society in Wales, and it was a question whether Liverpool and Bristol should not divide Wales between them.

The resolution was carried unanimously.

Mr. Bulmer moved the following resolution:—"By the establishment of such architectural provinces the architectural society of each district will have its local centre, and in time, by absorbing within its centre all architects of repute, bring into harmonious and united action the scattered and unorganised members of the profession, strengthen the position of all local practitioners, both professionally and socially, and enable arrangements to be made for extending throughout the country the advantages of the progressive examination now established by the R.I.B.A., and by promoting a systematic organisation for educational purposes, utilising and developing such means of instruction as may be available at and in connection with such centres, raise the standard of architectural education in all parts."

Mr. Murray seconded, and after a discussion on the present educational facilities in the various centres the resolution was unanimously adopted.

Mr. A. Heazell moved, "That, so far as the constitution of the R.I.B.A. and each society may permit, it is desirable that the president for the time being of each provincial centre shall have a seat on the Council of the Institute; and that this conference do represent to the Council the desirability of steps being taken to obtain such modification of by-law No. 25 as will enable this to be done."

Mr. Pick seconded the motion, which was agreed to, the representatives of the Institute expressing their concurrence.

Mr. E. Jones proposed, "That the secretaries of the several

provincial societies be requested to confer together to consider the boundaries of each province proposed to be attached to the respective centres for the purpose of provisionally defining the same, and then communicating the same to the Royal Institute."

Mr. Gibbs seconded, and the resolution was carried.

On the suggestion of Mr. Cates it was resolved that the secretaries meet in committee at the close of the present proceedings for the purpose, as far as possible, of agreeing upon a provisional report.

On the motion of Mr. Emerson, seconded by Mr. Drew, a vote of thanks to the Chairman for his conduct in the chair, and to the Liverpool society for their hospitality, was passed. The formal proceedings then closed, and the secretaries met in committee to discuss the boundaries of the several provinces.

GLASGOW CATHEDRAL.

AT the monthly meeting of the Glasgow Archæological Society, Archbishop Eyre read a paper on "The Western Towers of Glasgow Cathedral." His Grace expressed regret that the towers, which had been erected immediately after the original building in the fourteenth century, were pulled down about fifty years ago. They were, he pointed out, removed in an age when the style of architecture was imperfectly understood. The people had the impression they were built only just before the Reformation, and consequently were so plain that they were not worth retaining; and an agitation was started for their removal, in which the Lord Provost, the Dean of Guild and other officials took part. They proposed to replace them with something more ornamental. Drawings were obtained, and although the towers were satisfactory so far as Pointed architecture was understood at that time, they would now be totally condemned. The south-west tower—which was the plainer of the two, but venerable from its antiquity, having been used as the consistory house for two hundred years—was demolished about 1846. Two or three years later the north-west tower was pulled down, although a number of architects remonstrated very strongly against it, and petitioned the city authorities in favour of its preservation. There was an idea that another tower would be substituted, but that fortunately, His Grace observed, never was built. The removal of the towers reduced the length of the building, making it more like a very large parochial church than a cathedral church. Archbishop Eyre was unfortunately seized with a slight attack of weakness, and the concluding part of his paper was not read.

PREHISTORIC MONUMENTS IN STIRLINGSHIRE.

AT the last sessional meeting of the Stirling Natural History and Archæological Society Mr. A. F. Hutchison delivered a lecture on "The Standing Stones and other Rude Monuments in the Stirling District." In his introductory remarks Mr. Hutchison mentioned that the sites of these ancient monuments pretty nearly followed the contour of the hill ranges in the district, but no definite conclusion could safely be drawn from this fact, as the lower grounds could be more easily cleared of the stones, which would disappear under the culture of the land. One rather remarkable circumstance was that in nearly every case where these stones could be said to point in any direction, that direction was about 250 deg. magnetic north, the point where the sun rose during the summer solstice, and this suggested that the stones had some connection with sun-worship in pagan times. Cup markings were to be seen on several of the stones, and while these peculiar indentations were still an enigma to archæologists, Mr. Hutchison said he would not be surprised if they turned out to have some relation to the movements of the heavenly bodies. There was also reason to believe that these standing stones marked ancient burial-places, as cists had been discovered in the vicinity of some of them. Mr. Hutchison then proceeded to give details of a large number of stones which he had personally visited and measured. A few of these had been previously noticed, but the great majority had been hitherto unknown.

At the Meeting of the Glasgow Philosophical Society Mr. W. F. Murray, of the Caledonia Pottery, Rutherglen, read a paper "On a New System of using Gaseous Fuel in Firing Pottery Ware." In explaining his system he remarked on the extravagant use of fuel by potters and the economies that had been introduced by the adoption of scientific methods of obtaining and applying heat in the metal industries. Similar and greater economies, he said, awaited the pottery trade, which were to be reached by the same paths as had led to comparative prosperity among metal-workers.

NOTES AND COMMENTS.

ON May 11 the subscribers to the Architectural Publication Society will hold a general meeting which may be the final one. Originally the Society contemplated the production of a cyclopædia of architecture, but after a brief experience of the aid that was forthcoming it was decided in 1852 to limit the operations to the compilation of the "Dictionary of Architecture." Owing to the untiring zeal of Mr. WYATT PAPWORTH, that work was completed about a year ago. Under the circumstances, it was not to be expected that the pages of the Dictionary would express all the knowledge that relates to architectural subjects. The majority of architects, especially those who claim to be experts on any subject, naturally are inclined to keep to themselves any information they may have gained. Accordingly, it was necessary to make the most of books and articles in journals. Eventually the Dictionary became a sort of index to professional literature, and as such it ought to be useful to students. The critical standard became more restrictive during the forty years the Dictionary was in progress, and more was expected than could be furnished. Yet only eight complete sets of the Dictionary remain unappropriated. The committee are in hopes about the copies being speedily purchased, but it has been wisely decided that no reduction of the subscription of 21*l.* will be accepted. If after six months any sets remain on hand, it is proposed to present them to libraries or public institutions. Few societies, under similar circumstances, would escape financial embarrassments, but in this case Mr. ARTHUR CATES is able to announce that "the cash in hand will suffice to meet all current expenses until the affairs are entirely closed, and even should no further moneys be received by the sale of sets or parts, some small surplus will remain available to be appropriated as the meeting may direct."

THE French artists have reason to be gratified with the admiration of the Americans for their works. As it is now necessary to pay duties on pictures and other works of art it is easy to discover the value of the imports of that class. According to an official return, the value of French works for the year 1889-90 was 1,682,000 dols., for 1890-91 the value was 1,768,000 dols., and for last year 1,681,000 dols., or in three years French artists gained to the extent of over one million sterling from the United States. It is not impossible that a reduced valuation was placed on many of the works to save duty, and the expenditure would therefore be greater. Figures so satisfactory must give rise to the question, Why is the sale of English works of art among Americans so limited in extent? The French artists do not lay themselves out to captivate American purchasers, and yet somehow they succeed in doing so. The English works, we suppose, are considered too insular in character or too costly, and hence it is that foreign as well as American dealers do not trouble themselves about Royal Academy exhibitions, while they appear in force at the Salon.

It is not altogether advantageous for the fame of a French artist when his birthplace is a village or small town. The inhabitants may do their best to show their pride in the great man, but their efforts in that way sometimes are embarrassing. A case has just occurred in Mée, near Meulan. M. CHAPU, the sculptor, is a native of the place, and he presented a large number of models to the town. Having worked themselves up to an emotional pitch, the municipal council resolved that the treasures were to be inalienable while Mée endured. The magnanimity of the declaration is unquestionable, but if a visitor to the town cannot behold M. CHAPU's works, who can deny that they have been alienated? The models are placed in charge of the schoolmaster, and as long as he attends to his classes he cannot be curating. He is likely to suffer in the reports of his inspectors if he leaves his scholars. Under such circumstances, will M. CHAPU's gift produce much benefit for the embryo sculptors of Mée?

JOAN OF ARC is to have another memorial in the form of an equestrian figure. In the last Salon M. JULES ROULLEAU went into competition with M. FRÉMIET, for he

represented the girl in full armour, with the oriflamme in one hand and the sword in the other. The war-horse on which she was mounted appeared to be vigorous. The work was nearly successful in winning the médaille d'honneur for sculpture. It has been arranged that the work is to be cast in bronze and set up in the middle of the principal place of Chinon, the town where JOAN recognised CHARLES VII. in disguise amidst a crowd of courtiers and attendants. The pedestal will be designed by M. HENRI DEGLANE, architect. It is expected that the work can be placed in position some time during the year.

TO-MORROW (Saturday) will be varnishing-day at the Salon, when the price for admission will be ten francs. On Sunday next the charge will be lowered to two francs, and on Monday admission will cost five francs. During the afternoon of the Sundays in May half a franc will be charged, while in June there will be gratuitous admission on the afternoon of all the Sundays.

THE Opera House in Paris is so costly to the State, it is no wonder so many reformers are eager to adopt the English system, and to allow the managers to depend on the public without the aid of subventions. Everything that is necessary for the production of operas, or for upholding the house, runs to an amount of money that is startling to the French taxpayer. The latest proposal corresponds with those which have preceded it. An iron curtain became necessary, and of course it cost an enormous sum. It is found that hydraulic machinery is necessary to raise and lower the screen with expedition and smoothness. Of course the expense falls on the authorities. The Municipal Council will have to pay 20,500 francs towards the expense, and the State must contribute a similar sum. In England a manager would hesitate before he laid out 1,640*l.* for moving a drop-scene, and an English hydraulic engineer would, with the aid of a water company's main, get over the difficulty for a comparatively small sum. But in France practical science is fond of making a fuss about trifles, and so much will have to be done before the Paris curtain can be raised an inch, we are rather amazed that a couple of thousand of pounds sterling are not stuck on to the estimate. Whatever the outlay the taxpayers must meet it.

THE unoccupied land which is a legacy from the Metropolitan Board of Works to the London County Council is not a satisfactory sight to the inhabitants of London. It suggests either that the improvements were not needed or that the prices paid for property, and which determine the rent of vacant sites, were in excess of the value. The Corporate Property Committee have therefore proposed and the Council have sanctioned various conditions which it is expected will find favour with speculators and overcome their objections to treat for the unoccupied land. In the first place the option will be given to purchase the reversion of the property at a price to be fixed jointly by the Corporate Property and Finance Committees, not being less than twenty-five years' purchase; such option being exercised within five years, and only in cases to be approved by this committee and the Finance Committee, and where the buildings to be erected have been duly completed in accordance with the contract for letting and to the satisfaction of the architect; secondly, the term of the leases will be for periods of not less than eighty years and not more than ninety-nine years, the exact period being fixed in each case by this committee and the Finance Committee before the publication of the conditions of sale. It is also agreed that, subject to any modifications to be approved by the Public Health and Housing and Corporate Property Committees, the conditions as to sale of artisans' sites be amended so as to provide for buildings being constructed with good and suitable material and workmanship, to the satisfaction of the architect. All the properties are to be offered for letting or sale by public tender. The Council will in certain cases suspend the standing order which requires that, in the first instance, all properties shall be submitted to public auction. The officers of the Council are to be instructed to make the necessary arrangements for tenders for vacant land.

NEW PREMISES FOR THE IMPERIAL LIVE STOCK INSURANCE ASSOCIATION, LIMITED, 17 Pall Mall East.

THIS drawing represents a portion of Waterloo House, which is now being reconstructed from designs by Messrs. ESSEX, NICOL & GOODMAN, of London and Birmingham.

The ground floor and basement, with premises in the rear, will be occupied by the above Association, and the upper floors as offices and residential chambers. The front is executed in Portland and Dumfries stone, with Norwegian granite columns. The building throughout will be lit by electric light.

The contractors for the work are Messrs. SCRIVENER & Co., of Fitzroy Square, Regent's Park. The ornamental wrought-iron grilles, railings and balustrades by Messrs. BROWN & Co., and the lifts by Mr. GEORGE CLARKE. The stone carving and modelled enrichments have been executed by Mr. STEELE.

KIRKBRAE HOUSE, EDINBURGH.

THE illustration shows additions that have been made to an old and prominent house at the south end of Dean Bridge, Edinburgh, the property of Mr. STEWART. The site of this house is unique. It commands views towards Princes' Street, Firth of Forth, with Inchkeith in the distance, and Corstorphine Hill. None of these views can ever be built up.

Mr. YOUNG, Bryson Road, was the builder, and Mr. JAS. G. FAIRLEY, F.R.I.B.A., Edinburgh, was the architect.

In his "Old and New Edinburgh" the late JAMES GRANT said that Mrs. GRANT, of Laggan, lived in old Kirkbrae House. At that time her house was the resort of select literary parties, of whom Professor WILSON ("Christopher North") was always a member.

HISTORY AND DEVELOPMENT OF PATTERN DESIGNING IN TEXTILES.*

A GERMAN proverb says, "Kleider machen Leute," which is equivalent to the English "Fine feathers make fine birds." Another proverb runs, "We receive a man according to his dress and dismiss him according to his intellect." Accordingly, we find that it is a first principle in human nature to take special care as regards the attiring of the body. Savages only make a modest attempt by tattooing their bodies, while the civilised nations of all ages and countries have made an art of dressing themselves in splendid and rich costumes. This endeavour gave birth to an industry which, up to our days, has contributed in no slight degree to the prosperity of many towns and countries—I mean the textile industry.

It is not my purpose to read a paper upon the history and development of art and industry. My particular object is to give a very general summary of the evolution of textile design from the earliest times, and to show how many interesting details can be supplied by such an apparently insignificant subject as that of woven designs.

With regard to the period at which our investigations should commence, it might be considered that the art of usefully applying such perishable materials as the fragments of flax, the wool of sheep, and the fine threads spun by the silkworm, dates from no very distant time. But that is a great mistake.

We should be wrong in placing the birth of the textile industry at the commencement of the Christian era. We should be equally in error if we placed this period 1,000 years further back, to the time when Greek art was not yet spoken of, much less European culture. We can with confidence go back 3,000 years; that is, in all 6,000 years from the present time. Monuments of the early period prove to us that even then there was a culture in ancient Egypt which did not exclude the existence of a textile industry; on the contrary, its existence may be proved almost with certainty.

King Menes is said to have reigned over Egypt about the year 4000 B.C. He was accused by his successor of having enervated his people by excessive luxury. He was cursed by the priests (who also may be taken as a token of civilisation),

* A paper by Herr Paul Schulze, Conservator of the Royal Textile Collection, and Lecturer on Art in the Royal Weaving School at Crefeld, read at a meeting of the Society of Arts and published in the *Journal*.

and this curse was engraved upon a square stone. The author Ebers informs us how an Egyptian king's mother occupied herself with the study of physic, and concocted a lotion to make the hair grow. Now I think I may fairly conclude that a race of people who were in need of some means to make the hair grow more freely than in its natural condition, would not have neglected the protection and adornment of the other parts of the body; hence the existence of textile industry may be easily inferred. No remains of stuffs from this period are extant, but the paintings in the Pyramid show the Egyptians dressed in gowns striped with primary colours, blue, red and yellow. Besides this, little designs have been found which are evidently reproductions of woven patterns. There are little drawings of geometrical construction, combinations of lotus flowers, &c. There are also other motives in the designs from which we may conclude that they were applied to clerical vestures.

In a series of centuries we find that forms of certain animals, plants, &c., which were deemed sacred to religious service, were used symbolically for the designs for clerical vestments and antependiums. Hence it is probable that the Egyptians likewise used the forms of their holy animals and plants. This was particularly the case with the Assyrians, and the paintings of this race were very much like those of the Egyptians. I might, therefore, name some of the principal types which form the basis of Egyptian ornaments.

First, there are the buds and flowers of the lotus and papyrus plants, which were the symbol of the nourishment of the body and mind. Then the dung beetle or scarabæus. This insect has the remarkable habit of laying his eggs in excrement, with which it envelops the egg, and of forming a little ball. The beetle draws this ball after it with his hind legs until the surface hardens. The ball containing the embryo of a new life, which the heat of the sun will awaken, was to the Egyptians symbolical of the globe, out of which new life would spring, and of the minuteness of the Creator's work.

As the ancient Egyptians were sun-worshippers, their most sacred figure was the disc of the sun, mounting the sky on eagle wings. The Uraus serpent was the symbol of sovereignty over life and death, for the bite of this creature meant instant death. Beside these, many animals were sacred.

Another ancient state possessing culture was that of Assyria. The territory between the great rivers, the Euphrates and Tigris, was in early times the home of extensive industrial art. The Bible mentions the magnificence of old Babylon, and its circumference is said to have been about forty miles.

In the ruins of great Assyrian buildings were found plates made of alabaster, which were used for covering the walls. The prowess of the kings was shown on these plates. These give us plenty of clues to a textile industry; for we are able to ascertain perfectly well the manner in which the Assyrians made patterns for dresses, carpets and antependiums. On these plates the Assyrians are represented as being dressed in long loose gowns with fringes and embroideries to represent beasts fighting, fantastic forms of animals, bodies of lions with human heads and wings, human bodies with wings and birds' heads. Amongst these we see borders with stars, strings of roses, zigzag lines, winding curves, meandering lines, palmettos; and here also the disc of the sun with wings—the symbol of Assyrian sun-worship. A very characteristic ornament was the "Hom," the Tree of Life, which bears fruit like pomegranates.

The pomegranate plays a large part in the symbolism of many religions, as well as in the Christian religion. In ancient times it was the symbol of love: Jupiter makes the bridal Juno taste of pomegranates; Leah wanted to buy the love of Jacob—who loved Rachel better than her—with love apples, the smell of which animates love; and, lastly, the apple was the symbol of the generative power of nature, and was the forbidden fruit of Paradise. The Bible makes mention of weavings of an Assyrian character. Moses says of the makers of the ten large tapestries of the Tabernacle, which were ornamented with cherubim:—"Them hath (God) filled with wisdom of heart, to work all manner of work of the engraver, and of the cunning workman, and of the embroiderer in blue and in purple and in fine linen, and of the weaver" (Exodus xxxv. 35). About the official dress made for Aaron, Moses says:—"And they did beat the gold into thin plates, and cut it into wires, to work it in the blue and in the purple and in the scarlet and in the fine linen with cunning work. . . . And they made upon the hems of the robe pomegranates of blue and purple and scarlet and twined linen" (Exodus xxxix. 3 and 24).

A third great state of ancient culture in the far east of Asia is China. This empire has an important connection with the textile industry, being the native country of the most precious material for weaving, that is silk. In the year 2698 B.C. the consort of King Hongi, named Louitsen, is said to have invented the rearing of silkworms and the weaving of their threads. The strict custom of destroying with fire the dresses of the dead accounts for the fact that few or no remnants of old Chinese textile productions are preserved. Notwithstanding this, we are able to draw conclusions from modern drawings

as to those of times long gone by. A great characteristic of the Chinese is their adherence to ancient customs and a surprising power of resistance to foreign influences. With regard to art the Chinese are neither progressing nor falling back. They employ objects of all possible kinds, such as clouds, the waves of the sea, groups of rocks, shells, vases, &c., and all the flora. The lotus flower of the Egyptians is often used, as is also the peony, the symbol of the sky and the earth, deriving from the former flower perfume and from the latter brilliancy. We also find a number of fantastically-shaped animals, of which the dragon is a frequent figure—a marvellous creature, with the head of a chameleon, the horns of a stag, the claws of an eagle and the tail of a serpent. This dragon is the symbol of supreme wisdom. Its empire is all space, above the mountain tops, among the clouds, in the underground depths and in the air and the water. The dragon is the martial device of the Emperor and of the senior princes, possessing in this case five toes. The dragon of the junior princes not being so important has four toes, and that of the mandarins only three.

The device of the Empress is the phoenix, a bird with a peacock's tail and a head covered with protuberances. It symbolises a long and happy life. The Chinese horse, or "Khilin," has the body of a stag, the horns and tail of an ox and horse's hoofs. This marvellous creature appears in Assyrian art as a unicorn, and it may be traced up to the thirteenth and fourteenth centuries. Lastly may be mentioned the Chinese lion, or dog, named "Fo."

All these fabulous animals, together with specimens of the vegetable kingdom, and some very elaborate line compositions, form the elements of the extraordinary designs which the Chinese make use of in the decoration of their stuffs.

After considering the textile industry of the three oldest civilised nations in Asia and Africa, we turn to Europe, and give our attention to the nation which laid the foundation of European culture, that is Greece.

Until 1879, we are only able to draw conclusions as to the designs on Grecian stuffs from the decoration of old buildings and old pottery. Greek authors give a good deal of information upon the designs of these stuffs. Excavations made in South Russia, in 1879, have confirmed the supposition that no branch of industry or art has its own decorations, but the dominant style belongs to them all.

Amongst the articles found in the tombs, detailed and illustrated in the "Compte Rendu de la Commission Archéologique à St. Pétersbourg," in 1881, there were a number of fabrics, the age of which is denoted positively by inscriptions. From the tomb of a warrior of the fourth century a great cover, which was laid over the sarcophagus, was taken. It is about seven yards square. We see alternate mythological scenes and ornaments. This cover proves to be a Greek production, from the numerous inscriptions upon it in the Grecian language. The name Jocasta shows that scenes of the legend of Œdipus were being represented. The names Phœdra and Eulimene close by two women in violent motion, and the name of Atkaia point to the wrestling combat of Peleus with Thetis. The goddess Athene, armed with the protective ægis, and a lictor, returning from a chariot race, are also depicted on this cover. Another little piece of woollen material was found in a tomb, dating fifth century B.C. It is decorated with small zigzag, crosses, meandering lines and similar motives. In the same tomb which contained the large cover was found a piece of woollen material which was extraordinarily thin. One side of the fabric is bound with satin and the other with reps. The piece of stuff proves the great perfection of the Grecian textile industry. The patterns are woven upon a cherry-brown coloured ground in tapestry style. The design represents a series of five ducks with raised wings and heads, alternately turned to right and left. A beautiful dark green, whose brightness is very well preserved, is seen on the heads and necks. Other different fragments were found in the same place.

As these preserved fragments of the ancient Greek weavers' craft are of the greatest value to inquirers, so numerous literary references convince us of the cleverness of the Greek figure weavers. Their productions were worthy of a place by the side of their other artistic works—being of a high degree of merit. It is impossible to quote all the passages, but it may be sufficient to mention two of them.

Ovid, in his *Metamorphosis* of Arachne, says it was a pleasure to observe Arachne winding the wool and curling and twisting it into fine threads. She contended with Pallas Athene in a trial of their skill in weaving. Each puts her loom in a separate place, and stretched the fine threads thereon. The combatants hasten to their work. Pallas Athene weaves the Castle of Cecrops, standing on the rock of Mars. Twelve immortals are seated on their thrones, in austere solemnity, with Jupiter in their midst. Neptune, the sea god, alone is standing, and with his trident he strikes the unheaven rock, from which the salt water gushes forth. Pallas Athene is shown, furnished with the defending ægis, and having on her head a helmet and in her hand a pointed lance. At the place where the lance has

pierced the ground, a green olive tree, bearing berries, is sprouting. The work is surrounded by a garland. The gods look at it with astonishment.

It is very interesting to compare this woven picture, described by Ovid, with the splendid sculptured work executed by the celebrated Greek sculptor Phidias for the pediments of the Parthenon, now the temple of the goddess Athene, on the Acropolis.

England is fortunate enough to possess, in the far-famed Elgin Marbles in the British Museum, the original remnants of this work of Phidias. This sculpture also shows the representation of the quarrel concerning the name of the town of Athens.

But Arachne wove the story of Europa carried away by the bull. The latter seems to be really living, and the sea to be heaving. In addition, Arachne wove Asteria seized by the flying eagle, the loves of Leda and the swan, and other similar scenes. An ivy garland went round the border, with flowers interwoven. Ovid reports, moreover, that Pallas Athene was not pleased with Arachne's work; on the contrary, she punished her by changing her into a spider, ugly indeed, but a skilful weaver. This was Arachne's punishment for having had the temerity to remind the daughter of the father's amorous adventures. A passage in the *Odyssey* also gives a clear image of Grecian designs. Ulysses describes to Penelope the dress he wore on his departure to Troy. The dress of the noble Ulysses was of a purple colour, and rough in texture, with flashing embroidered front. A spotted doe is struggling under the forelegs of a savage-looking dog. The astonishment of all beholders is excited by the manner in which the dog embroidered in gold is strangling the doe, while glaring at it most ferociously, the latter meanwhile endeavouring to regain its freedom. This embroidery is very interesting, because we find among the stuffs of the thirteenth century a very similar design.

Such weavings of Roman origin as have been preserved date from the time of the Roman emperors. A very rare little piece of silk—perhaps belonging to the time before Christ—is preserved in the church of Valeria, at Sitten, Switzerland. The design shows a female figure, sitting on the back of a sea-dog, and under the latter an acanthus stalk. This stuff from Sitten, the Greek fragments already mentioned as being found in Southern Russia, and perhaps two or three other little remnants in various museums, are the only known remains of textile products of the time before Christ.

To arrive at the place where probably the oldest weavings of the Christian era were produced we must again return to the country which has shown itself so well able to preserve the treasures entrusted to it. I mean Egypt. In Sakkarah and Akhmîm, in Upper Egypt, large cemeteries have been discovered in recent years. The dead bodies contained in them were not enveloped in strips of linen, as were the old Egyptian mummies, but were dressed in the garments they had worn when alive. We obtain a complete picture of the costume of this period. But we are more interested in learning the materials of which the garments are made. There is the towel-faced material, which when used for costume was worn in the winter. In the height of summer, when steeped in fresh water, the peasants would use it to wrap round the wine amphora to cool its contents. They had also a kind of wool rap, a compact twilled woollen material with a woven broad purple stripe, woollen cloth, evidently woven over rods, looking like velvet with an uncut pile. But our greatest interest will be excited by the woven bands crossing each shoulder and running vertically down the front and back of the robe, and by the round and square pieces of cloth, the medallions, which were the signs of rank. These articles were woven in tapestry style, with many-coloured threads, in wool. There are ornamental and figure-pieces in great variety—bull-fighters, slingers, bowmen, mounted hunters with lances, hunting-lions and leopards, and a variety of animals, such as wild goats, hares, birds, &c. Further on, medallions with biblical scenes, perhaps the history of Joseph in Egypt, or another one showing Abraham about to sacrifice his son Isaac.

Not only were woollen fabrics found in excavating these tombs, but also silk materials. We find little designs, not larger than the size of a pea, composed of little lozenges, hearts and clubs. In squares or circles occur horsemen or dancing-girls similar to designs on Persian fabrics mentioned later on.

At present it is hardly possible to say positively whether these fabrics were manufactured in Persia or whether they were woven in Alexandria, Antioch or Byzantium. Similarly we are not yet able at present to determine the age of these goods. At all events we have reason for supposing them to be some of the oldest-preserved woven products of the Christian era, belonging to the time from the third up to the eighth century.

Now let us consider the Persian woven designs. At the time when the Romans were losing more and more of their independence, owing to the enervating results of their social life and the lassitude of their rules, and when from these causes the Roman Government was hastening to its ruin, the Persian

empire in Asia was building up a new civilisation upon the ruins of a culture then long gone by. In the year 226 B.C. Artaxerxes I. took in hand the government of all Central Asia. He founded the family of the Sassanides, who reigned in Persia 426 years. The greatest prince of Persia was Chosroës Anurshirwan, 531-79. During his reign commerce, industry and weaving of a high character flourished. Some original fabrics, kept till the present day as covering for relics, prove the great perfection of this Persian textile industry. If we analyse the designs upon the Sassanide weavings, we mostly find large circles standing in rows one upon the other. The points of contact are covered with roses, smaller circles and polygons. This is a very characteristic design, and one which occurs in Persian and Byzantine fabrics of the fourth up to the twelfth and thirteenth centuries. In the church of St. Servatius at Maestricht there is exhibited a small collection of fabrics of the Middle Ages. Amongst them is a very brilliant specimen of Persian weaving skill. A broad circle decorated florally encloses two Persian kings hunting lions on horseback. Hunting-scenes very often appear on Eastern fabrics, because the Orientals are great sportsmen, and we shall see similar scenes until the end of the Middle Ages. The riders and huntsmen are not always arranged in circles; we also see men on horseback, sometimes with wings, placed in rows without circles, or in squares or polygons, great lions gravely stepping in order one after the other, or two of them facing one another. Very interesting examples of Sassanide fabrics are preserved in the treasuries of the churches on the banks of the Rhine and in Aix-la-Chapelle, in several museums, such as the South Kensington Museum in London and in the Museum of Industrial Art in Berlin.

We now return from the Persian land of wonders to European ground, and consider the silk-weaving of Byzantium. This new capital, which at the time of Constantine the Great had taken the place of ancient Rome, endeavoured to emulate the old city in all matters appertaining to art. In Byzantium the artistic capabilities of the Old World were concentrated. Here the flickering spark of art was fanned to set ablaze a new art-life later on; whilst in the Western countries, owing to the violent disturbances attending the migrations of tribes, the influences of art were decaying more and more. In the beginning of its development Byzantine, or early Christian art, was a hybrid formed by the influences of the Western nation which ruled over Byzantium and by those of the Asiatic races subjugated by the Roman. With the government of the Emperor Justinian I. (527-65), a new epoch was inaugurated, and a new style created.

The Byzantine style flourished up to the early part of the thirteenth century (1204). At this period the decline of this splendid and pompous style commenced, but the inhabitants of the eastern Roman Empire continued under its influence until the time when the Turks conquered this once mighty empire (1453).

The reign of the Emperor Justinian was the prominent feature of the Byzantine Empire, as well in art as in history. Justinian I., not without reason, has been compared with Louis XIV. Both showed the same activity and capability, both were animated by the same bigotry, both were under the influence of petticoat government, and in the states of both sovereigns ambition for military glory and a great love of pomp, nourished by taxes, produced the same results. Justinian employed all the financial schemes of modern politics to swell the public revenues, such as every description of tolls, duties on eatables, state monopolies, &c. Of the latter, the monopoly of manufacturing splendid silk goods is particularly remarkable. The rearing of silkworms in Europe cannot be traced back earlier than the reign of Justinian. Before this time the silk was imported from India and China, in which countries its production was guarded as a great secret, and the export of eggs of the silk moth was attended with severe penalties. The legend runs that two monks conveyed in their hollowed pilgrim staves some eggs of the silk moth and seed of the mulberry tree, so important for its nourishment, when returning from a pilgrimage from distant China in 555. These were the germs from which an industry was to be evolved, and to which Europe owes a large part of its present opulence.

Justinian was able to appreciate the great importance of silk weaving and silk industry. He brought into his own manufactories silk weavers from those countries which were in competition with him.

We have seen how the Persian kings of the family of the Sassanides established silk manufactories in the same manner as Justinian. They paid great attention to the silk trade, rightly valuing their favourable geographical situation, which placed them midway between the East and the West. For this reason Justinian engaged first-rate Persian weavers for his imperial factories. It followed, as a matter of course, that these weavers did not immediately resign their own tastes, and thus we find, especially in the earlier part of this period, great relationship between the Byzantine and Persian drawings. Of course there was a reciprocal movement in this matter, because

the Persian kings also made use of the excellence of the Byzantine textile industry at that time by engaging weavers from Byzantium. There is an additional factor in this likeness between the Persian and Byzantine woven designs; the latter also show us figured pieces surrounded by large circles.

In the treasury of the church at Maestricht there is kept a piece of stuff which belonged to the garment of St. Servatius, the patron of this church, in which he was buried. The figured part of this design is surrounded by connected circles having a diameter of a quarter of a yard. Within the circle two brothers stand upon a Doric column, perhaps Romulus and Remus, or the two Dioscuri, Castor and Pollux. On each side of the column a bull is being sacrificed. Two angels pour out a libation.

According to Dr. F. Bock, a praiseworthy investigator and collector of textiles, this fabric is the only piece of silk which gives a representation of a heathen sacrifice of animals. The technical detail is remarkable. We observe four colours in the woof: the ground is dark crimson; the outlines of the floral ornament and of the figures are covered with dark violet purple; the carnation and some parts of the garment are woven in yellowish-white silk; and, lastly, green is employed on the garments and for the floral ornament. We can assign the manufacture of this very interesting fabric to the fourth century A.D.; and it is quite possible that the material was really part of the dress of St. Servatius, judging not only from the design, which is characteristic of the period, but also from other reasons, such as the traditions attached to this rare piece of silk and its discovery and preservation. A powerful argument is furnished by the great resemblance of the ornament in the circumference of the circle to the ornament, similarly placed, which appears on a piece of silk found in a Coptic tomb in Egypt. The design is undoubtedly the same, and, as Coptic fabrics have been found with papyrus documents, which are dated from the fourth century, there is no reason to doubt but that this material, attributed to St. Servatius, did belong to him. This is the more probable, as that saint went on a crusade from Asia Minor to the north of Germany, Belgium and Holland.

Another celebrated fabric is preserved amongst the treasures of the Aix-la-Chapelle Cathedral. Here also we see large connected circles, with diameters of over half a yard. The figured centre, a team of four horses, is sure to relate to the chariot races, which were so popular at the time of Justinian that the two great political parties of Byzantium used to wear the colours of charioteers. Hence the name of the parties "blue" and "green."

A scene very often represented in designs of the seventh and eighth centuries is that of a man fighting with a lion. It may be the fight of Hercules with the Nemean lion, or Samson strangling the lion, or finally the struggle of Christian martyrs with wild beasts in the Roman amphitheatre.

It is not possible to describe here all the woven pieces made under the influence of Byzantine art up to the thirteenth century. It may be stated that most of the designs were composed of animals facing one another and surrounded by graceful ornament. All possible varieties of animals were made use of. In old inventories of churches we find mentioned the chasuble with lions, the eagle dress, the chasuble with elephants, &c.

An interesting brocade, with pattern of lions, is preserved in the South Kensington Museum. Dr. Franz Bock, in Aix-la-Chapelle, one of the best connoisseurs of ancient textiles, says in his book "*Die liturgischen Gewänder des Mittelalters*," with reference to this design:—"If in Christian art the royal lion of the tribe of Judah represents our Saviour, which fact is undoubted, then in this design our Saviour would be Lord and Commander of the whole creation, and it would be possible to find a reference in this design to the Psalm, 'Thou wilt stalk across serpents and salamanders.'"

A cope with large eagles is preserved in Brixen Cathedral in Tyrol. On a red satin ground we see large eagles in a dark greenish black colour. The actual size of the eagles in the pattern, taken from one wing to the other, is 20 inches.

A most interesting pattern is to be seen on the splendid silk stuff in which the bones of Charlemagne were enveloped in the Aix-la-Chapelle Cathedral. The ground colour is red, the elephants and ornaments white, yellow, blue and green. The diameter of the circle is 32 inches. Besides these fabrics bearing the large designs, several remnants of materials are preserved, which show smaller patterns of geometrical construction. There are pieces of small octagons, roses, little crosses and such like. The quarrels of the image worshippers and image breakers in the eighth century perhaps had their influence upon figured textile design. Even art was outlawed, being considered an accomplice of idolatry. But this is a matter I leave to others.

Remains have been preserved of another class of silk goods which have their interest from a technical point of view. Owing to the method employed in binding the warp and the weft, the finely-drawn designs, composed only of outlines, merely appear as though engraved upon the shiny satin surface. It is very

probable that these fabrics are also examples of Byzantine textile art. The period at which they were produced is determined by the places where they were discovered, and by the traditions attached to them. In the cathedral of Xanten, near the lower Rhine, a yellow chasuble of St. Bernard, and in Mayence Cathedral, a green chasuble of St. Willigis are shown. In the Royal Museum of Industrial Art at Berlin, and in the Royal Textile Collection at Crefeld, are exhibited pieces of the garment in which the German Emperor Otho the Great (936-73) was buried. The dyeing of the materials forms a very interesting part of the examination of the Byzantine textile manufacture. Without entering into detail, it may be shortly stated that purple was the most valued colour of the Middle Ages. It comprised six shades of colour, from the darkest violet to the purest violet-red. The imperial purple possessed a deep, dark tone, like that of the violet flower. In the times of the Roman emperors the real purple from the *murex* shell-fish was worth its weight in gold; the use of this colour was confined exclusively to the imperial court and the church. The purple of Alexandria and Tyre has been famous from the earliest times.

The consideration of textile design subsequent to the decay of Byzantine art brings us to the art of the Mohammedans. With the spread of Islamism a great revolution of culture took place. Owing to the rapid propagation of Mohammed's doctrines, his adherents, within 100 years after his death, had obtained a footing eastward as far as the banks of the Ganges, and westward over all the northern part of Africa, as well in Sicily as in sunny Spain. The Arabs transported into their newly-conquered dominions not only their creed but also their culture and science. In Spain splendid palaces arose, all the pomp and luxury of the East expanded, and industry and commerce reached a height never before attained.

(To be continued.)

LOCKS AND SAFES.*

(Concluded from page 264.)

RENAISSANCE work pure and simple now claims our attention, and we are able to point to some very pronounced specimens, as regards keys especially. A serrurier, named Mathurin Jousse, published a book on his trade at Paris in 1627. He discourses on the behaviour of apprentices to their masters and of their treatment by their masters; tells how he prepares his metal, and how he shapes his tools; descants on the shapes of padlocks; gives names to multitudinous key-wardings; describes a file-cutting machine, and finishes up with an invalid's wheeling chair, and artificial arms and legs made in sheet-iron. The book is fully illustrated, and one of his four keys is reproduced in diagram. Another of his keys is almost exactly like the celebrated Strozzi key from Florence, now in the possession of Baron Adolphe Rothschild, and said to have been made by Benvenuto Cellini; but M. Piot, a French writer of authority, doubts this. Jousse incidentally says that ordinary padlocks with spherical bodies (here is one) were easy to make, but when they had two hasps, and a key going in each side to secure each hasp, they were difficult. Here is an exact copy of one of these, the original being in possession of a friend in Germany. Jousse also says that a lot of time was unnecessarily wasted through apprentices having to spend so much over their guild work required for initiation. Would that there were some such high standard to be passed now. In Germany, apprentices formally smoked themselves into their guild, using pipes in shape of keys. Jousse's escutcheon plates, whilst no doubt true to his times, show classical grotesques painfully conceived, but even they are not as repellent as some of the later German ones. These latter have been illustrated in a series of process photos, lately published at Munich. In these mere surface scratches do duty for bold incision, and hardly any *repoussé* is used to give force to designs that need it.

In viewing these two periods, the Française and Renaissance, we almost lose sight of the mechanism in the art. With the exception of the French letter padlock (about 1615) security seems to have been sought in elaborate arrangements of internal guards or "wards." These previously mentioned were projecting pieces of metal, plates and curved pins that swept round from the bolt to one side of the keyhole, and were fastened generally in a separate casing or box, hence called "box of wards." The key was shaped to clear them, and so get at the bolt. The bolts being usually "spring," it was not necessary that the key should turn right round, so a good many wards were used that would not have been possible otherwise. Here is one set of wards illustrated in a book published in 1767 by Hamel du Monceau. Had the key made a complete, instead of only a partial revolution, it would of course cut these wards right off.

The puzzle padlock, as is well known, was improved by a French mechanician, Regnier, at the end of the last century, but this was only one of the many things he did in combination locks. Anyone interested in the details of these will do well to study Bottermann's folio, 1781, and may then be surprised to see how little there is new under the sun. When keys were made of irregular shapes in cross-section and passed into their locks through keyholes cut to fit them—that is externally as distinct from being internally warded—there is considerable variety. The most curious one I have met with is illustrated in diagram, and was made for presentation to Napoleon I.

The work done by the English during the Mediæval and Renaissance periods is not as noticeable as that produced on the Continent. South Kensington has one show-case of English locks and several of French and German. Even the well-known lock-plate on St. George's Chapel, Windsor, is ascribed to Quintin Matsys (Wyatt), and we know that although, at an early date, the grilles around the tombs of Henry III. and of Eleanor, Edward I's queen, were done by Englishmen, foreign workers were being constantly invited over, even down to the end of the seventeenth century, when Tijou designed the gates for Hampton Court Palace. Tijou, by the way, illustrates four perfectly charming key bows. They are delightfully delicate and free in design. But I think to England is due the credit of decorating the stock lock, and certainly the combination of pierced bright or black iron over the strongly marked grain of oak is effective.

To get a good idea of the keys of the last century, one cannot do better than visit the collection of chamberlain's keys, bequeathed by Mr. Octavius Morgan to the British Museum in 1888. They come from Spain, Portugal, various German States and Denmark. The times and courts of our own king Georges are well represented amongst these eighty odd specimens. Two unnamed ones are double-ended pipe keys, drilled right through from end to end, and have circular-sliding bows that can be pushed up over either bit to make a handle for the other; they are nearly all gilt, and their bits are in many cases beautifully warded; as for the art of their bows, with the exception of some of the earlier ones, they are decidedly heavy. In at least one of them the emblematic and official idea is so paramount that the key-bit has disappeared altogether, leaving only the bow and stem; this is but natural, for often disused limbs lose their functions and in a few generations vanish.

These emblems of office suggest to us the symbolical ideas that have, as it were, hung about keys in all ages, prominent among them being that attaching to the presentation of a key to the Jewish rabbi on his institution, representing that in future the duty is his of unlocking and exhibiting sacred truths to the people. To those doctors of the law who did not do their duty came the condemnation:—"Woe unto you, lawyers! for ye took away the key of knowledge." There are many other scriptural references to the symbolical use of the key as an emblem of power and authority that will at once occur to us. These ideas, too, survive in folk-lore and superstitions, keys being used as talismans to prevent the entry of witches into houses or held by gipsy-women when prophesying or fortune-telling (Dillinger).

The spirit of applied science that sprang up one hundred years ago did not leave locks untouched. First came Barron, so altering and duplicating the old pivoted tumbler, or catch, that it or they had to be lifted to an exact height to free the bolt; and then Bramah, whose ingenuity was as much, or more, displayed in the machines he made to construct his locks as in the locks themselves. Many other names there are of subsequent inventors, all duly chronicled, with their mechanical ideas in the Patent Office, and more often known to us by this means than by the extent to which their locks have survived. Many inventions have lived for a time, but the Chubb lock, originally patented in 1818, has met with popular and continued appreciation, and now has a stronger vitality than ever. There is always a section in every community that demands things of the highest grade, and to this section the Chubb lock has always appealed. May I here be permitted to state, simply as a matter of fact, and without egotism, a curious matter bearing on this point of quality; it has a philological aspect, too. In the Straits Settlements the Chinese dealers have introduced a new adjective into their pigeon English; they speak of a "Chubby pair of trousers," or "a Chubby pot of jam," meaning that it is the best of its kind. The Chubb lock first achieved its notoriety chiefly from the fact of its containing a mechanism called the detector, by which the owner could tell if anyone had been lifting up its tumblers too much. This it still has in a slightly different form. Its tumblers vary in number, from six up to ten, according to the size and nature of the lock (a few small sizes have less than six). Contrary to the popular idea that the kinds of Chubb lock are comparatively few in number, the variety is so great that it takes a long experience to master their details.

I will now turn back to the early strong box, for its development into the safe and steel room is so closely connected with locks that the two may, in their modern aspect, be treated

* A paper by Mr. Harry W. Chubb, read at the meeting of the Society of Arts on April 12.

together. Dr. Schliemann, in "Troy and its Remains," tells us he thinks he found remnants of King Priam's treasure box, and gives an illustration of its probable key. In the Middle Ages cellars and vaults for storing valuables were protected by wooden doors sheathed with iron plates. Chests were made of oak or other hard wood, often strongly bound with iron bands, and sometimes, as in a beautiful specimen preserved at Knowle House, Sevenoaks, covered with leather. The German, or so-called Dutch, chests one meets with, made of little iron plates, rivetted together under bands, owe their peculiar construction to the fact that large sheets of iron were not produced. The rolling mill was unknown, and plates and strips had to be simply hammered out. Mounted on the inside of their lids were numerous spring bolts, all worked from one warded central key. Padlocks, too, were often used to secure them. In chests of this kind the goldsmiths of Lombard Street kept their bullion when in the reign of Charles II. London merchants first adopted the banking system. The foundation of the Bank of England in 1694 marks the commencement of a distinct epoch in the idea of credit that prevailed in England. This idea, permeating every branch of society, has developed with the country's increasing wealth, and is indicated by the present numerous joint-stock and private banks. Cast-iron safes and doors, easily fractured by concussion, were in vogue well into this century, but gave place to those made of rolled iron. This is now in its turn being displaced, the recent strides in the manufacture of that purer form of iron, called steel, having made it possible to substitute this more efficient and reliable material.

It is not my intention to describe in detail the requirements of a good safe, nor to weary you with the difference in quality of the various English makers. My purpose is rather to place before you some particulars of the latest developments here and in America. Despite our advanced civilisation, and the fact of lessening crime, the ingenuity of safe-makers has to be constantly at work to baffle the army of skilful scamps called burglars. Commencing with the productions of American makers, it is necessary to note that they draw a very sharp distinction between safes intended to withstand fire and those to resist burglars. Where a safe is wanted for both risks, a small burglar safe is usually fixed inside one of the other kinds. Anyone, with but little trouble, can force open an American fire safe, and the purchaser is perfectly aware of this. Whilst the outside is made of rolled iron or steel, the inner portion of the door, containing the lock and bolt work, as well as the rebating into which its numerous rebated edge shuts, is generally made of cast-iron. These castings are fairly tough, and are not brought through to the outside. The thickness between the inner and outer skins is filled up with materials selected for their non-conducting qualities. These are probably more various than those used for the same purpose in England, and include hard-setting cement concrete, which gives a certain amount of additional strength to the safe, compositions in a constant state of moisture, mixtures of dry plaster, asbestos and other finely divided materials. Some commercial salts are often added to the dry mixtures for the sake of the water of crystallisation which they contain, and which they give off in the form of aqueous vapour when heated in a fire. The Americans, as a rule, make their safes with a greater thickness of fireproofing than is done here, in order, I presume, to cope with increased risk. Added to this, they often introduce internal sheet-iron doors behind the main doors, entirely covering up the fittings of the safe, or else a layer of sheet-iron or prepared wood is fastened to the inside of the main door a little apart from it. Keyless combination locks are used in place of key locks to fasten the main bolts. These, having only one spindle, are operated by a revolving dial on the other face of the door, the edge of the dial being generally marked off into a hundred divisions. To open the lock the dial is revolved until the predetermined numbers to which the internal discs of the locks have been set are successively brought to a fixed mark. These discs or wheels, three or four of which are in each lock, are called tumblers—somewhat erroneously, in my opinion, for we have already seen what tumblers, whether falling pins or pivoted levers, really are. There is one variety of American combination lock that is a very interesting mechanical study, for its inventor has cut himself adrift completely from the past in designing it. As, however, it would take too long to describe it, I will simply refer you to the wall diagram, and to a sample of it on the table.

In American safes intended to resist burglars several thicknesses of steel of different degrees of hardness are employed, and all joints between the plates are carefully made and closed or covered with forged bands. To give extreme hardness so as to resist drilling, cast metal similar to Speigeleisen, and therefore capable of being chilled, is in some cases run in between the outer and inner plates of the safe. The strength of some of the United States safe deposit vaults is very great, resulting partly from the emulation of different owners as much as from necessity. One system recently introduced proposes to use solid blocks of chilled iron, grooved, keyed or bolted

together, not less than 10 inches thick. Upon the doors of other vaults a good deal of ingenuity is concentrated. One I recently saw in the country of big things is 8 inches thick. This was made not of cast-steel or iron, but of rolled plates of varying degrees of hardness, rivetted or bolted together. It measured about 7½ feet by 4 feet, and was hung upon crane hinges, shutting into its seating in the front of the vault with numerous rebates and three double grooves and tongues. The fit was so accurate that you could almost cut a sheet of paper between the meeting edges of the door and its surrounding frame. American practice adheres almost universally to the round bolt, made so as to revolve freely, with the idea of thereby frustrating any attempt to saw it through. The bolts are secured by two or more keyless combination locks, and by a chronometer lock, commonly called a "timer," which controls the bolts independently of the others. No doors of safe deposits, bank vaults or safes of importance are without "timers," and it is computed that there are not less than from fourteen to fifteen thousand in use. If a burglar, either by force or fraud, obtains the secret of the numbers of the combination locks, he cannot open the safe provided the "timer" be on guard. The owner, when closing his door for the night, sets his time-lock to run off guard at any hour he selects the following morning, say at nine o'clock, and at that time or after he can open the door. Timers are all capable of being set to run seventy-two hours, so as to go over Sundays, or, if necessary, from Saturday to Tuesday. To prevent the possibility of a lock-out, through the failure of springs or other accidents, modern timers have three distinct movements in them, any one of which is strong enough to run the lock off guard should the other two fail. One gentleman, Mr. Holmes, has contrived an ingenious electrical attachment to counteract the effects of a lock-out; another, Mr. Dalton, makes his timer work in conjunction with an auxiliary combination lock, which can only be brought into action when the timer stops. Here is a timer with three movements, which I hope presently to show you at work on the screen by powerful reflection. The existence of the timer, together with the popular reliance placed on it, has enabled the American manufacturers to meet a new method of attack. Discarding drills, blowpipes, gunpowder and other antique aids to their profession, burglars have within the last few years been studying the advantages of nitro-glycerine. To introduce it through the door they have pressed or wedged in the spindles, either of the locks or the bolt handles (English makers generally taper these the opposite way, viz. outwards). Though it is not possible to drive the spindle right in, enough space is obtained to inject the yellow fluid. Then, piling books and office furniture in front of the door, they await the blow-up. Of course, this method, involving as it does some noise, is not well adapted for city operations. What I am saying is not romance. It has been attempted sometimes successfully, at least twenty-five times. I should be very sorry to think that, by learning such facts as these, any English burglar might be induced to risk his life as well as his liberty, for it is not the duty of any safe-maker, with a well-ordered mind, to instruct thieves how to do their work. All I want to do is to show you how this has led up to a new application of the timer. You will see from this method of burglary it became desirable to do away with all spindle-holes through the door, and the problem was, then, how to work the main bolts. This has been solved by the use of powerful spiral springs, enclosed in a box mounted inside the door. One set of springs is for throwing the bolts, and there is another for retracting them. When the door is open the springs are wound up, or rather compressed, ready for action. From the nature of the mechanism it is impossible simply to wind up one set without the other. On closing the door, the first set throw out the bolts, either immediately by means of a contact trigger mechanism, or else by a small auxiliary time movement, and the door is locked for the night. The triple timer controls the second set of springs by means of catches, and at the appointed hour next morning releases these, and the main bolts automatically fly back. Thus ordinary locks are quite dispensed with, and reliance is wholly placed in the stored power of the springs, governed by the timer. This arrangement is sometimes applied in duplicate. It might be thought that the catches, being somewhat delicate, could be disarranged by external explosion, but this has been proved to the contrary by experiment. I have heard the objection raised that under this system the bolts, not being always held out by a rigid mechanism, may under certain circumstances be worked or pushed back; but in all work with any pretensions to good quality, it is just as difficult to get at the bolt-heads as it is to get through any other part of the safe, or its door. The fact that there are not less than two thousand of these automatic arrangements in use at the present day in the United States shows that they are entirely practical.

In England there is a large variety in the nature of the materials employed for the better class of safe-work. The object, as everyone knows, is to use a material which shall be sufficiently hard to resist drilling or other cutting instrument, and yet at the same time sufficiently tough so as not to become

fractured under percussion or pressure. To the system of running hard metal in between softer plates may be added that of case-hardening—that is, converting into steel the outer surfaces of iron plates of good quality, so largely done now with the working parts of machinery. Plates, or slabs, are also made up upon the model of war-ship's armour, *i.e.* with layers of high carbon steel welded and rolled in between layers of iron or mild steel. The high carbon steel gives the resistance necessary to keep out cutting instruments, the softer material contributing the toughness. Usually and preferably these layers are continuous, so that no part of the structure is unprotected; they are generally five in number, being either three of hard or two of soft, or *vice versa*. If made with two of hard and three of soft, the outer layer of hard steel is covered by one of the soft, but this does not interfere in the least degree with the efficiency of the hard steel, or modify the molecular change that takes place in it during the final chilling process. If, however, a hard steel face is desired, it is just as readily made as the other. It is the presence of carbon in steel which makes it hard, and steel with '6 per cent. of carbon in it is therefore more difficult to work than that with the usual percentage of '17 to '18. I mention this degree of carbon—'6 per cent.—because it is a kind of dividing line between steel that is easily worked and that which gives some difficulty, although not by any means insuperable, to hand tools. Safe-makers look with considerable interest upon the experiments of metallurgical experts in the production of steel alloys, so as to obtain a perfectly homogeneous plate, having the two properties of hardness and toughness sufficiently developed for their purposes.

In treating these armour-plates in the workshop I have applied special emery-wheel machinery, so as to produce exactly the sizes required after hardening, and thereby obviate the errors of fitting that are unavoidable if the plates be first planed in the ordinary way and subsequently hardened. I always dispense with jointing wherever it is possible to bend, or in any other way turn a corner; and these armour plates are as readily and as satisfactorily bent under the round-edge system of safe-making as if they were simply mild steel plates. Movable emery wheels are also applied to cleaning off the heads of composite rivets, and generally producing smooth and level surfaces where necessary.

Fastening the door into its frame has received considerable attention from all English safe-makers, resulting in bolts that claw, clutch, hook, screw, expand or interlace. Those shown on the diagram of the Chubb door do not shoot forward at right angles to the four sides, but move out at angles of 45 degrees; on each edge some go one way and some the other, thus pointing in opposite directions. By this method they form compound dovetails between the door and its frame, holding the two firmly together in case of attempted wedging. The diagram shows a door of somewhat unusual strength, the bolts being secured not only by double acting key locks, but also by keyless locks and a "timer."

It is often possible, in the lighter and weaker kinds of safes—safes, I mean, that can be opened with either a pickaxe or a sardine tin opener—to so "make them up" that they may deceive any but experts. This is done by giving the safe an appearance of constructional solidity it does not possess, by showing a thick front all round the door, the door itself seeming to be a plate of solid metal. In reality the appearance is produced by small packing bars, to which, on each side, are fastened sheets of iron no thicker than two folds of brown paper. The joints are filled or covered with "stopping," and careful painting—sometimes slightly scratched in order to produce an attractive idea of secondhandness in the minds of unwary customers—completes the semblance of a safe. It is easy enough to make these as heavy as the real things by using some weighty material for the fire-resisting (?) filling. What reliance can be placed upon them has been proved in many a fire, for amongst the *débris* of ruined walls one sees them lying about literally in pieces—their contents nowhere.

The safeguard against all this is of course to deal only with makers of standing and repute, who will say exactly how the safes of their various qualities are made, the thickness and material of the plates, &c. Even then it is not an easy task to make a selection, and the puzzled purchaser sometimes seeks professional and independent advice to decide between the rival claimants for his custom. Safe-makers are constantly being asked how long their safes will stand a fire, and how long they will resist burglars. To these queries it is almost impossible to give decided and definite answers. The more ready a maker is to give a guarantee that his safe is absolutely fire and thief-proof, the more cautious should a customer be in accepting the statement. Nothing is perfectly proof against fire and thieves, and the degree of protection obtained largely depends upon the sum of money expended.

Electric burglar-alarms are often used as adjuncts for security in many banks, the system employed being that in which a constant current is maintained, as distinct from the ordinary dwelling-house alarm, where the bell is only rung if

the circuit be completed instead of being broken. But it is not sufficient to insure the bell ringing simply if the wires be cut, for burglars with any knowledge of their business will join the wires outside the object protected, as as to leave the electrical circuit still complete. Hence a reliable system should give the alarm even if the wires be joined as well as cut. The little model I have here, of a strong-room door fitted up with such an alarm, illustrates this. By turning either of the keys or by breaking either of the wires, or by even joining the wires, the bell at a distance is rung. There is, therefore, a positive advantage in leaving the wires exposed, so as to invite tampering with them. Electricity may also be applied to other objects in connection with strong-room or safe-work, such as locking up gates at a distance, but it must always be borne in mind that wherever a constant current is used the batteries require periodical attention.

ELECTRIC LANTERNS.

IT may be interesting to many teachers in England to learn that a feature of the lectures upon architecture at the New York Museum of Art this winter has been the efficient working of the two electric lanterns used to throw upon the screens views illustrating the various subjects discussed. The plan of using two screens and two lanterns has proved a signal success, doing away with many slight delays in shifting the slides. In the comparison of architectural forms of any given period, with earlier or later examples, the twin screens were especially valuable.

Electric lanterns have been brought up to such a pitch of excellence, that any real and striking improvement attracts notice and wins special praise. The twin lanterns used to illustrate these lectures were of the most improved pattern, and had one feature whose excellence was proved by its effective working, and which has not been attached to any electric lantern until within the last three months. This feature is the setting of the carbons at an angle, with the lower one further toward the front of the lantern than the upper one. The wires were so connected that the arc leaped from the lower to the upper, bringing the luminous point upon the front side of the upper carbon, affording an unobstructed pathway for the light straight ahead out of the lantern. In other words, by setting the carbon pencils on a slant the carbons did not stand in their own light.

The good effect of this arrangement was seen in every picture projected upon the screen. The light was intense, and never shaded or wavering. This arrangement of the carbons was the idea of Mr. Alfred L. Simpson, formerly the vice-president of the Society of Amateur Photographers of New York, who has operated the electric lamps used to illustrate these museum lectures at the request of General Di Cesnola.

The lanterns themselves were of the latest pattern, consisting of the usual three parts—the lens frame at the front, the condenser frame in the middle, and the frame for the electric lamp or the oxy-hydrogen jet at the back. The various parts of the lantern could be adjusted for any sort of work, including that required by microscopy, and could be tipped up and down and sidewise with the greatest ease.

The electric current used was a continuous current of from 110 to 125 volts, the lamps passing about 12 amperes of current and 45 volts. Each lamp was supplied with a variable resistance coil, or rheostat, and a volt meter attached to the wooden standard of the lantern kept the operator continually informed as to the strength of the current that he was getting. The cost of the whole outfit, including the two lanterns, rheostats and volt meter, was about 600 dols. No equipment of the sort previously made has combined the idea of the tilted carbons, the special arrangement for drawing out the front of the lantern so far, with so great general adjustability and compactness. Mr. Simpson has been gratified by receiving personal congratulations upon his work by the trustees of the museum and from every lecturer of the season.

ARCHÆOLOGICAL SURVEY OF LANCASHIRE.

UNDER the auspices of the Society of Antiquaries and of the Lancashire and Cheshire Antiquarian Society, and with the assistance of antiquarians resident in the various localities, Mr. William Harrison of Manchester is compiling an archæological survey of the county. This will include a map on which the sites of the various ancient remains are indicated and a topographical index, arranged in alphabetical order, giving exact references to the local histories and to papers in transactions and periodicals respecting these antiquities. The introduction will give a chronological arrangement. The survey does not come down to a later period than the Conquest, although some doubtful remains, possibly of later date, are provisionally included. It will probably surprise many, says the *Manchester Guardian*, to know how numerous are the relics of antiquity recorded as on Lancashire soil.

Beginning with the misty and undefined pre-Roman period, there are no drift implements, but neolithic implements have been found at Aldingham, Barrow, Besom Hill (Oldham), Bleasdale, Bolton, Broughton-in-Furness, Bull Hill, Cartmel, Claughton, Crow Knoll (Oldham), Dalton, Dean, Dendron, Droylsden, Flixton, Furness, Goldshaw, Gleaston, Hawkshead, Haydock, Hopwood, Irlam, Kirkby Ireleth, Knowl Hill, Lancaster, Liverpool, Longridge, Manchester, Marton, Milnrow, Middle Hill, Newton-le-Willows, Oldham Orford, Pennington, Pendle Hill, Pilling Moss, Preston, Rampside, at many places in the extensive ancient parish of Rochdale, at Roosebeck, Royton Park, Salford Sharples, Silverdale, Stainton, Tatham, Todmorden, Tooter Hill, Turnshaw Hill, Ulverston, Wardle, Wavertree, Wegber, Woodlands and Wray. Neolithic floors have been found at Bull Hill, Tooter Hill, Knowl Hill, Middle Hill, Blackstone Edge and Readycon Dean. There are rock basins at Boulsworth Hill and Warcock Hill, near Burnley. Prehistoric interments are known at Aldingham, Allithwaite, Blackburn (Revidge), Bolton, Broughton (Manchester), Cark, Cartmel, Catlow, Cuerden, Extwistle, Grange, Hasty Knoll (Blackrod), Hawkshead, Kenyon, Kirkby Ireleth, Lancaster, Manchester, Over Darwen, Roose, Scales, Tong, Walmsley, Warton, Wavertree, Weeton, Winwick and Yealand. Canoes have been found at Martin Mere, Preston, Penwortham, Rufford and Barton (Stickens); British coins at Liverpool; and bronze implements at Aldingham, Calderbrook (Mow Road), Cartmel, Cuerdale, Dalton, Furness, Kenyon, Lancaster, Marton, Page Bank, Pilling Moss, Preston, Read, Rixton, Risley, Southworth, Sharples, Stainton, Tong, Wegber, Winmarleigh and Winwick. There are megalithic monuments at Birkrigg Common, Kirkby Moor, Warton and Turton.

We come now to the Roman period. The chief stations were at Manchester (Mancunium), Wigan (Coccium) Ribchester (Bremetonacum), Overborough (Galacum), and Lancaster (? Alone); whilst the Portus Setantiorum is believed to have been near Wyremouth. The minor stations were Walton-le-Dale, Kirkham, Burnley, Ringstones, Twist Castle and possibly at Blackrod, Castle Head, Castercliff, Downholland and Dalton. Temporary camps are set down as at Mellor, Langho, Portfield, Prestwich, Kersal and Walmsley. There was a dock at Carnforth, and according to Watkin, Botontini at Heapy, Langho, Preesal, Prestwich, Quarlton, Ulverston (Mountbarrow), Moat Hill (Warrington). (Arkholme, Melling, Hornby and Halton, which are claimed to be Saxon burhs, will be mentioned later under "Earthworks.") There are no villas, except perhaps one at Hornby. The cemeteries are at Manchester, Lancaster, Ribchester and Wigan, and a pottery at Lancaster. Roman coins and miscellaneous antiquities have been found at the many places named in Watkin's "Roman Lancashire," and also at Broughton (Manchester), Didsbury, Droylsden, Hawkshead, Oldham, Poulton-le-Fylde, Slences (Oldham), and Ulnes Walton. The authenticated Roman roads are:—(1) From Wilderspool, Cheshire, entering the county at Warrington, and proceeding by Wigan, Preston and Lancaster to the border of the county, and thence through Westmorland to Kendal and Carlisle; (2) Manchester to Wigan; (3) Manchester to Ribchester and Overborough, continued to Witley Castle, Cumberland; (4) Manchester to Slack, Yorkshire; (5) Manchester to Stockport, continued thence through Cheshire to Buxton; (6) Manchester to Kinderton and Chester, entering Cheshire a few miles from its commencement; (7) Ribchester to Kirkham, and thence (as is supposed) to the Portus Setantiorum; (8) Ribchester to Burwen Castle, near Skipton, Yorkshire, passing near Clitheroe and Downham; (9) Ribchester to Galgate, near Lancaster; (10) from the Lancaster and Kendal Road, near Carnforth, by Wyke, Flookburgh, Sandgate and Conishead (crossing the Kent and Leven Sands) to Dalton, and then crossing the Duddon Sands into Cumberland. The following additional roads will be marked as probable:—11, Manchester to Littleborough and Ilkley (with a reference to Blackstone Edge); 12, Blackrod to Mellor; 13, Blackrod to the Manchester-Wigan Road near Eccles; 14, Gorton Bridge (Salford), through Barton to Wilderspool; 15, Walkden to Barton-on-Irwell and Stretford; 16, Castercliff to Langho; 17, Portfield to Burnley, continued to Ringstones Camp; 18, Burnley, by the Long Causeway into Yorkshire; 19, Castercliff southwards towards Twist Castle and northwards through Colne; 20, Dalton to Ambleside by Satterthwaite; 21, Lancaster to Overborough; 22, Lancaster to Ivah, and perhaps further eastwards; 23, Kirkham to Elswick; 24, Melandra (Derbyshire), by Staley Street to Doctor Head (Yorkshire). The following roads are not proposed to be marked:—Downholland to Ditton (only supposed by Watkin), Dane's Pad at Pilling (probably Mediæval), Reddyshore Scout Gate (no certain traces of Roman work). Fragments of road will be mentioned in index under Brindle (Pepper Street), Dalton, Fleetwood, Hawkshead, Ulverston.

To the Anglo-Saxon period belong the sculptured stones found at Barton (Ship Canal), Bolton, Burnley, Halton, Heysham, Lancaster, Whalley and Winwick; the interments

at Claughton, Inskip and perhaps Langho. The burhs at Aldingham, Arkholme, Melling, Hornby, Halton, are included below under earthworks. Coins and miscellaneous antiquities of this period have been found at Cartmel (Castle Head), Chipping, Harkirke, Cuerdale, Halton, Lancaster, Liverpool, Manchester, Stalmine, Stretford (it is not certain that the Lancashire Stretford is referred to in this connection). The battlefields are Douglas, Maserfeld, Langho and Bruanburh—some of them matters of controversy.

In addition to the foregoing there are of course many remains of a miscellaneous character which cannot safely be assigned to any definite period. Among these are included the earthworks at Castercliff, Walmsley, Mellor and Campfield (Salford), supposed to have been Roman camps; that at Warton Crag, thought to have been a British camp; those at Arkholme, Halton, Hornby and Melling, which were set down by Watkin as Roman Botontini, but, like the Moat Hill at Aldingham, are now believed to have been Saxon burhs; the mounds at Heapy, Langho, Preesall, Prestwich, Quarlton and Ulverston, also set down as Roman Botontini, and mounds at Newton-le-Willows, Pennington and Chanderton, which are probably tumuli. There are, besides, traces of mounds or entrenchments at the Moat How (Carnforth), Rufford, Ince Blundell, West Derby and Woolton, and the dyke known as Nico Ditch. There are also numerous walled enclosures, cairns and structural remains of uncertain date, including walled enclosures with cairns, small camps, ramparts, cairns, tumuli unexcavated, bloomaries (*i.e.* ancient forges or smithies), ring mounds, sometimes termed stone circles (not, however, being megaliths) and foundations. These are mostly in the Furness district, but a few are noted in other parts of the county, particularly bloomaries, at several places in Rossendale and near Rochdale, and at Royton, while ancient habitations or other remains have been found at Penwortham, Pilling, Hardhorn, Stretford (the Great Stone) and Wigan.

The preparation of this archæological work has entailed a large amount of patient labour and much correspondence upon the compiler. It is desirable that all possible corrections and additions should be made before it assumes its permanent form. Any communications on the subject may be addressed to Mr. William Harrison, 112 Lansdowne Road, Didsbury.

THE SURVEYORS' INSTITUTION.

THE following student candidates have passed the examination for the professional associateship:—

Walter Ely Andrews, Ely Villa, St. Faith's Road, West Norwood, S.E.; Thomas Harrison Caffyn Bannister, Limehurst, Hayward's Heath, Sussex; Harry Greaves Bradshaw, 26 Demesne Road, Alexander Park, Manchester; Frederic Kersey Debenham, 80 Cheapside, E.C.; Edward William Eason,* 43 Bishopsgate Street Without, E.C.; Herbert Phillips Fletcher, Anglebay, West Hampstead, N.W.; Percy William Gray, 4 Arundel Villas, Station Road, Cambridge; Frederick Algernon Green, 28 and 29 St. Swithin's Lane, E.C.; Frederick Kirk Hawes, North Collingham, Newark, Notts.; Percy Cave Holiday, Bicester, Oxon; Archibald Wyndham Irvine, 10 St. George's Terrace, Gloucester Road, South Kensington, S.W.; Walter Nike King, 17 Akeman Street, Tring, Herts.; John Roy Lancaster, 28 and 29 St. Swithin's Lane, E.C.; Harry Edward Maddox, Milford House, John Street, Hampstead, N.W.; Frederick Charles Thomas Mann, 9 Malwood Road, Balham Hill, S.W.; Alfred John Martin,† 19 High Street, Chelmsford, Essex; Samuel Martin, Bolney Grange, Havelock Road, Croydon; Charles Edmund Neighbour, Fair View, Bradbourne Park Road, Sevenoaks, Kent; George Lloyd Pain, Silverdale Vicarage, Carnforth, Lancashire (Cirencester); Charles Bates Punchard, Underly Estate Office, Kirkby Lonsdale, Westmoreland; Joseph Townson Sly, 88 The Parade, Leamington Spa; Ernest Allen Stapledon, Lakenham, Northam, Bideford, Devon (Cirencester); Frederick Hubert, Thompson, The College of Agriculture, Downton, Wilts.

The following non-student candidates have also passed the examination for the professional associateship:—William John Almond, jun., 15 Brunswick Square, Camberwell, S.E.; Louis Hewitt Bailey, Blagrove Street, Reading, Berks; John Evans Bidwell, St. Mary's, Ely, Cambridgeshire; Joseph Harold Birley, Spring Bank, Pendleton, Manchester; Richard Elwyn Birch, Maes Elwy, St. Asaph, North Wales; Percy Morris Bodger, Cardington, Bedfordshire; Wm. Lobin Trant Brown, 32 Pembury Grove, Lower Clapton, N.E.; Reginald John Cox, 9 Albert Road, Brighton, Sussex; George Ernest Champion, Lyewood, Boughton Monchelsea, Maidstone, Kent; Alfred William Cooper, 10 Dingwall Road, East Croydon; Harry Vernon Darbishire, Oakdene, Cowden, Kent; George Willoughby David, The Hendre, Llandaff, Cardiff; Cyril Froodvale Davies, Froodvale, Llanwrda, South Wales (Cirencester); Frank Delamare, 34 Great George Street, S.W.; Walter John

* Institution Prizeman, 1893.

† Special Prize, 1893.

Easton,* 1 Colville Road, Bayswater, W.; John Edmonds, Bushby, near Leicester; Harry Charles Fitt, 7 Western Road, Brixton, S.W.; George Thompson Hewett, Puttenham, near Guildford, Surrey; Sydney Jeffree, Howard Lodge, Atkins Road, Clapham Park, S.W.; John Jenkinson,† Barrow, Broseley, Shropshire; Charles Arthur Kennett, Warrior Square Railway Station, St. Leonards-on-Sea; Charles Edmund Lart, 4 Upper Tichborne Street, Leicester; Cecil Wynn Marriott, Upham Rectory, Bishop's Waltham, Hants; Lewis Osler Mathews, 15 Waterloo Street, Birmingham; James Frederick Mellor, 110 St. James's Street, Brighton, Sussex; Henry Monson, 15 Palace Street, Buckingham Gate, S.W.; Daniel Morrison, 3 Old Palace Yard, S.W.; Gerald Donald Morrison, The Oaks, Reigate, Surrey; James Noel Norman, Dunkery Lodge, Putney, S.W.; Howard Parson, 24 St. George's Road, Beckenham; Fred. W. Pearce, 2 Avondale Villas, Haydon's Park Road, Wimbledon; John Thomas Pegge, The Guildhall, York; John Moeles Pyke-Nott, Waterloo House, Ely, Cambridgeshire; John Dougal Roney-Dougal, Estate Office, Ackham-in-Cleveland, Yorks; Arthur Reed Sale, The Grange, Botcherby, Carlisle; Sydney Saker, 3 Bank Buildings, Hastings, Sussex; George Farquharson Seddon, 4 Colinette Road, Putney, S.W.; Frank Braybrook Smith, 23 Brunswick Place, Cambridge; William Clowes Sows, Horsley, Leatherhead (Cirencester); Albert Henry Staley, 21 Coton Road, Nuneaton; Samuel Clifford Tee, 86 Grosvenor Road, Highbury New Park, N.; William Bott Tyler, 55 Lawford Road, Kentish Town, N.W.; Robert Edward Waldrum, 6 Manor Road, Leyton, E.; William James Watson, 13 Pembroke Square, Kensington, W.; Charles Henry Edward West, Fernville, Fortis Green, Finchley, N.; Edward Willis, 124 High Street, Eton, Bucks; Ernest William Malpas Wonnacott, 106 Lancaster Road, W.; Robert Garmondsway Wrightson, Hurworth-on-Tees, Darlington; John Walter Wyles, Melrose, Cambridge Park, Wanstead, Essex.

The following professional associates have passed the Fellowship Examination in Division IV.:—Benjamin Percy Abrams, 29 Abbey Road, St. John's Wood, N.W.; Frank Amos,‡ 1 Parade, Canterbury, Kent; Frederick Herbert Bancroft, Kay's Chambers, 26 Cooper Street, Manchester; Frederick Maurice Beadel, 97 Gresham Street, E.C.; Archibald Turner Bellingham, Dover's Green, Reigate, Surrey (Cirencester); Septimus Beven, 56 King Edward Road, South Hackney N.E. (Cirencester); Arthur Body, 15 Princess's Square, Plymouth, Devon; Ralph Hollinshed Brady, 17 Warren Street, Stockport; Alexander Burnett Brown, The Bays, Hampton Wick; Arthur Macdonald Brown, Tring, Herts; Sidney Crawford Buckland, Windsor, Berks; George William Cobham, 1 and 3 Edwin Street, Gravesend; John Thomas Crier, 2 Surreyville Gardens, Castelnau, Barnes; Frank Bridgewater Debenham, Cheshunt Park, Herts; Horace Bentley Debenham, Cheshunt Park, Herts; Benjamin Belgrove Franklin, Holly Walk, Luton, Beds; Alexander Goddard, Knighton Spinneys, Leicester (Cirencester); Frederick William Lawley, 165 Strand, W.C.; Henry John Leaning, 90 Grove Lane, Denmark Hill, S.E.; John Wilfrid Lee, Vestry Hall, Hampstead, N.W.; Jas. Henry Mellenfield, 45 Cazenove Road, Stoke Newington, N.; Henry Herbert Robinson, The Cottage, Heathfield Park, Willesden Green, N.W.; John Edward Tory, 29 Fleet Street, E.C.; Percival Fox Tuckett, 2 Basinghall Street, E.C.; James William Tyler, Elm Villa, Trinity Road, Upper Tooting, S.W.

The following candidate has passed the Direct Fellowship Examination in Division V.:—Henry Blackburn, 6 Queen Anne's Gate, S.W.

LEEDS ARCHITECTURAL SOCIETY.

THE seventeenth annual meeting of the Leeds and Yorkshire Architectural Society has just been held in the Law Institute, Albion Street, Leeds, Mr. G. B. Bulmer, F.R.I.B.A., president, in the chair. The report, which was read by the hon. secretary, Mr. W. Carby Hall, said that the society had continued to expand in membership, in the area from which the members were drawn, and in the usefulness of the work done. The Council had agreed with the Leeds Master Builders' Association upon a form of contract agreeable to both parties, but, learning from the Council of the Royal Institute of British Architects that a committee appointed by the Institute were in consultation with the Institute of Builders on the subject, and that it was hoped shortly to issue a form of contract which would be acceptable for use throughout the country, further action in the matter was postponed. The council had had under consideration the subject of unrestricted bill-posting in Leeds, and, after obtaining information on the matter from various Continental centres, a memorial had been presented to the Leeds County Council, in the hope that it would strengthen their hands in dealing with the question in the new Consolidation Bill. The Town Clerk, in reply, had thanked them on

behalf of the Council for the material they had supplied, stating that it would be of advantage to the Parliamentary Committee, and promising that the matter should have careful attention. A memorial had been sent from the Society to the Council of the Institute concerning the anomaly at present existing in the election of Fellows of the Institute, by which young architects of the age of thirty who had been in practice for seven years could present themselves for election, and so evade the examination, which was obligatory upon candidates for the Associateship. A memorial, generally signed by the members, was sent to the Leeds School Board last year with reference to the remuneration for professional services offered in the conditions of a competition for a new Board School. A deputation also waited upon the Board, but the Building Committee could not see their way to deviating from the course already laid down, and a large number of the competitors withdrew from the competition. The Council had under consideration a scheme promulgated by the Institute for the dividing of the United Kingdom into architectural provinces, for the promotion of architectural education by the systematic organisation of the various classes upon technical subjects. The Society now numbered 121 members—31 honorary members, 50 members and 40 Associates, as against a membership of 110 last year.

On the motion of Mr. W. Hall Thorp, seconded by Mr. W. H. Beevers, the report was adopted.

The following were elected the officers for the ensuing year:—President, Mr. G. B. Bulmer; vice-presidents, Mr. H. B. Buckley and Mr. J. H. Greeves; hon. treasurer, Mr. W. A. Hobson; hon. secretary, Mr. W. Carby Hall; hon. librarian, Mr. W. J. Mettam; members of Council, Messrs. W. H. Beevers, E. J. Dodgshun, F.R.I.B.A., G. F. Danby, A. Marshall (Otley), C. H. Thornton, W. Watson (Wakefield); auditors, Mr. F. W. Bedford and Mr. A. E. Kirk.

GENERAL.

Baron Nathaniel Rothschild has presented his château at Richeneau and grounds in the Styrian Alps to a society in Vienna, to be converted into a hospital for chest diseases.

The Bognor Local Board have decided that plans and specifications for new buildings are to be laid on the table in the board-room two or three days before they are formally submitted for approval.

Mr. J. Honeyman has been reappointed a governor of the Glasgow Technical College for a period of five years.

The Prix Duc, founded for the promotion of academic architecture, has been awarded to M. Camut for his reconstruction of the baths at Mont-Dore.

Mr. Thomas Stone, architect, died in London on Sunday in his fifty-seventh year.

The Bill promoted by the London and South-Western Railway Committee has been approved by the Committee of the House of Commons. It authorises, among other projects, the construction of a new graving dock at Southampton and the creation of 1,333,333*l.* additional share and loan capital.

M. Puvis de Chavannes has obtained a commission to paint decorative panels for one of the Boston libraries. The subjects were not prescribed to the artist.

Mr. F. Cherry, formerly a pupil of Mr. W. M. Mitchell, of Dublin, has obtained the second premium of 100*l.* offered by the Government of South Africa for a design for the new museum in Cape Town. There were twenty-four competitors.

A Letter was read at the Synod of the Presbyterian Church of England, held in Manchester on Wednesday, from Mrs. Lewis and Mrs. Gibson, of Cambridge, offering a site at Cambridge for a college and promising to bequeath a sum of 15,000*l.* towards the erection of buildings, in the event of the Synod deciding sooner or later to transfer the college from London to Cambridge.

The Plans prepared by Mr. John McKissack have been selected by the Glasgow Improvement Trustees, for the blocks of buildings which are to be erected at Osborne Street.

The Cardiff County Council have resolved that application be made to Lord Bute for acquiring the land lying between the county club and the north side of the intended post office, and the whole length of Park Street parallel with the point first started from Westgate Street, and that his lordship be asked at what price per acre he will be disposed to part with it for the erection of a public building.

The Great Fire at Messrs. Judd's Premises.—Those who are interested in fireproof construction may see a most remarkable proof of the utility of fireproof floors at Messrs. Judd's premises. The ground-floor of the main warehouse was constructed by Messrs. Homan & Rodgers, and not merely resisted the intense heat caused by the fire above and below, but now is actually intact and sustaining the *débris* of the four upper floors, printing machinery, walls, &c., piled to a height of some 30 feet.

* Driver Prize, 1893. † Consolation Prize given by President.

‡ Crawler Prize, 1893.

The Architect.

THE WEEK.

THE Manchester people do not believe in the proverb about the uselessness of examining the grinders of a gift horse. Sir JOHN GILBERT'S present of pictures to the city has not given general satisfaction. The London Corporation, it is said, obtained the best prizes, and, what is more hard to endure, Liverpool contrived to have the next chance of selection. What was left fell to Birmingham and Manchester. Sir JOHN GILBERT apparently had little to do with the distribution. Birmingham, on the other hand, is more than satisfied. At the meeting of the city council on Tuesday it was unanimously resolved to accept gratefully the most generous gift of Sir JOHN GILBERT, and the twenty-two works were declared to be a valuable and important addition to the permanent collection in the Art Gallery. It was also suggested that the artist should be made a freeman of Birmingham. Can it be that the gifts were judged by different standards in the two cities? Birmingham apparently perceives they can be utilised by students of art. It may be that in Manchester the interest for sightseers was the desired quality, and in that respect the works probably are less valuable than some of the recent purchases.

THE thirteenth annual report of the council of the City and Guilds of London Institute is satisfactory enough to gratify all who have an interest in "technical education" that will be deserving of the name. There is steady and continued, if not startling, development in all branches of the Institute's work. There was some increase in the students at the Central Institution, while at the last technological examination there were 8,534 candidates against 7,416 in the preceding year. The fees received at the Central Institution amounted to 4,821*l.*, at the Finsbury College 3,490*l.*, and at the South London School of Technical Art 127*l.*, while the corresponding expenditure was 12,511*l.*, 9,352*l.* and 1,266*l.* The technological classes and examinations throughout the country cost in addition 7,117*l.* It will be evident that every year involves the governors and council in responsibility for large sums of money. The balance reserved last year was only 1,825*l.* The art classes at Finsbury, it is said, show a very striking advance, particularly in figure painting, original designs in black and white and in modelling from the life, but Professor SYLVANUS THOMPSON does not hesitate to acknowledge that "the advance in quality, which is the gratifying feature of the year, is mainly due to the influence of two or three excellent students, who have been several sessions in constant and earnest attendance, and are now making a name for themselves and for the college that has trained them by the artistic qualities of their work." He says there is a distinct demand for the establishment of a special class for house-painters and decorators. Students are also eager to have the modelling studios open on additional nights. Mr. SPARKES is so fond of repeating his remarks about favourite students who have gained success, it is difficult to make out what has been the progress in the South London School of Technical Art; but the council inform us that "the work done at this school was fully up to the standard of previous years." The council may be congratulated on their success, and it would be well for the country if other promoters of technical education in Great Britain could point to results that are equally beneficial.

SOME members of the Arts Committee of the Liverpool Corporation visited London a couple of months ago to make applications to artists for the loan of pictures for the next autumn exhibition, and spent from nine to ten hours daily during twelve days (Sundays not excepted) in their task. They visited two hundred and forty studios. The circumstance suggests the efforts which have to be made to get together a collection for Liverpool. For the painters must be doubtful about the advantage that will arise to

them to repay their trouble and risks. The official report says:—"Some complaints were heard from constant and loyal supporters of the exhibition that they received no encouragement to contribute, from the fact that year after year their works were returned unsold." It has, however, to be admitted that the statements are undeniably true. The committee therefore implore persons of wealth and taste, who value the autumn exhibition as a means of spreading a love for art, to buy a picture during the season, and thus prove to artists that their pecuniary as well as their artistic reputation will be served by supporting the exhibition. The appeal has a good intention, but it sounds odd to find art going a-begging in that way in a city which is assumed to have some importance.

DAYLIGHT in Manchester is precious, and it is not easy to understand how building owners can have the hardihood to take away from their neighbours an infinitesimal portion of a commodity that is so rare. The Temple Chambers Company, Limited, having disregarded rights of the kind, are now in the disagreeable position of finding that they have erected their building too loftily. Opposite the company's new building in Mulberry Street was a chapel and presbytery. As the street is narrow and the chambers have many storeys, the priest's house was darkened. But as the company believed that the sun so arranged his course for their benefit as to deprive the priest of light for only two hours of a morning, they were indifferent to his inconvenience. What could a priest want with sunlight? As for diffused light, that of course was of no consequence, although the occupants of the presbytery were deprived of a half of their former allowance. The priest applied for an injunction, which has been heard in the Chancery of Lancashire. Mr. ROBINSON, Q.C., who presided, said there would be a sensible and appreciable loss of light in the plaintiffs' premises if the premises were allowed to be completed. He could not compel the plaintiffs to sell their legal right of light and the comfort and enjoyment which sprang from it for a money payment. He must in the exercise of his discretion grant an injunction restraining the defendants from further proceeding with the erection, and ordering them to pull down that part of their building which interfered with the plaintiffs' enjoyment of light and air. In view of an appeal, he suspended the mandatory part of the order till July 2. It is not easy to see how a case of the kind is to be settled, assuming that the defendants cannot have the decision reversed, unless by paying whatever is asked. The house cannot be sold apart from the church, and besides, it would not be easy to determine the loss from having a darkened light during services. The company's purposes, on the other hand, can only be served by a high building. The case is therefore complicated, and it is a pity more foresight was not exercised before the works were commenced.

A MEETING of the County Council of the North Riding of Yorkshire was held in Northallerton on Wednesday, when it was decided to rescind the resolution which was recently passed:—"That the plans of the new offices and a council chamber submitted by the Standing Joint Committee be approved, and that having regard to the numerous and rapidly increasing duties imposed upon the county council and its committees and officers, the county council are of opinion that the existing county buildings are both inconveniently situated and wholly inadequate for the due transaction of the county business; that the limited area of county land adjoining, if sufficient for a present addition, would be insufficient for any future addition to such buildings, and that it is unwise to expend any money in an attempt to enlarge or improve such buildings." The following resolution was adopted:—"That the present county buildings, with the land adjoining, afford ample space for providing all necessary accommodation for the transaction of county business, including that of Quarter Sessions and Council." It was also decided to consult an architect, and obtain plans showing what could be done with the Council's site.

ARCHITECTURE AT THE ROYAL ACADEMY.—II.

THE Chartered Accountants form a very modern corporation, but they have been wise to assert their influence by having a council-house erected which will bear comparison with many of the older guild-halls of London. Mr. BELCHER, by means of a capital sectional drawing, shows the council-chamber and library. A severe type of Italian with plain Tuscan columns has been adopted for the interior, but it is so treated as to become far more dignified than would be a later and less restrained style. The introduction of a large pictorial composition behind the chair enhances the effect. The Glasgow Athenæum, by Messrs. BURNET, SON & CAMPBELL, becomes remarkable by the towerlike division, which we suppose contains the staircase, and which is marked by vertical lines, like the tower in the Offices of the Clyde Trustees, by the same architects.

There are architects who find it is profitable to imitate Mr. WATERHOUSE's style, and examples of their adaptations may be found in the exhibition. His two drawings will therefore be closely studied. In both there is much vigour, one cause being the care that is taken with the vertical lines. The National Provincial Bank of England, Piccadilly, might be classed as Italian, but that must not be taken as implying that it is derived from any building in Italy. The arch has been avoided and the only curved lines are found in the pediments of the windows, which form a sort of attic. In the offices of the Refuge Assurance Company there is more restraint, but Mr. WATERHOUSE should know what is most suitable for a Manchester atmosphere. The "Banking Premises, Parliament Street," by Mr. HUNTLEY GORDON, was evidently designed with a view to secure attention for the building in a street where there are others to compete with it. There is a tower, surmounted by a statue of Justice; much surface-decoration and a bright terra-cotta is proposed for use. Messrs. T. M. LOCKWOOD & SON's banking premises in Chester has the advantage of a corner site, which is well utilised. The bank may be said to exemplify one kind of modern Renaissance, and it is of a form that suggests security. To design a building that will stand beside the fragment of INIGO JONES's Banqueting Hall is no easy task. The Royal United Service Institution, by Messrs. ASTON WEBB & INGRESS BELL, does not suggest that it was intended to surpass the older work. It is in a more modern but less architecturesque manner, and probably the dignity of the hall will be enhanced by the new building. Messrs. KIDNER & BERRY have an unpretentious bank at Daventry.

A foreigner can hardly fail to be astonished by the number of drawings of churches, church furniture and church decoration which appear in the Academy. Mr. UNSWORTH shows a fine screen of wood in Perpendicular style for St. Mary's, Horsell. In the interior of the new church, Staines, by Mr. FELLOWES PRYNNE, we see another type of screen, and we are glad to say it does not suggest an obstruction. The new chapel of the Cancer Hospital, by Mr. A. GRAHAM, could not easily be made more simple; the patients probably are not supposed to be in a mood to admire ornate work. Messrs. MORRIS & HUNTER, in their design for St. Andrew's, Ayr, reveal an admiration for Flamboyant details. Mr. E. T. HALL has an "extension" of a church at West Dulwich, which probably means the addition of a vestry; but in all such cases a plan should be given to define the new work. Mr. E. KIRBY's St. John's, High Leigh, Cheshire, does not depend on its height for interest, and the use of timber in the walls brings it into correspondence with the secular work of the district. We suppose Mr. SEDDING's experiment of employing an ultra-Roman church, with Roman equipments, has had the effect of deluding organ-grinders and their friends at Clerkenwell, and carried them under the influence of reformed doctrines, for in the new Church, Mission-house and Schools for Italian Protestants, Clerkenwell, the type adopted is also Italian, but Gothic. The church itself may recall to the strangers some buildings they have seen in their villages, but the convenience and completeness of the group must be strange to them. The church, house and schools at Bexhill-on-Sea, by Mr. P. H. TREE, do not form one of those stereo-

typed groups which are common. The main building is kept low, but from the size of the principal window the congregation cannot suffer from that dim, religious light which oculists and sentimentalists admire, and the number of flying buttresses without is a provision for light and shade, which nowadays is too often neglected. Mr. VACHER's design for St. Peter's, Abbeydale, represents a small Perpendicular church with a nave and two aisles, which is pleasing.

As Mr. J. O. SCOTT's design for organ-front, St. Mary Abbots, Kensington, appears in perspective it is not easy to judge of the elements which give character to the organ; but in a building which, by its extreme regularity and coldness, seems to symbolise the mechanical character of the age, the slightest effort at originality would appear reprehensive. The chancel of St. Peter's, Bushey Heath, by Mr. NEALE, appears in two views, and from the treatment we assume it is contemplated to raise some storeys hereafter on the chancel, which was made massive enough to sustain the weight.

The St. Joseph's Church, West Hartlepool, by Messrs. DUNN & HANSOM, is careful and unpretentious. The tower is not of excessive height, which is an advantage, for in Roman Catholic churches that part can rarely be completed. Mr. M. B. ADAMS's Pulpit, St. Michael's Church, Chiswick, deserves to be recommended for general adoption by manufacturers of church furniture, only it has too much variety and character to be turned out by a machine. It is small, and therefore not only does not occupy much space in a building, but there is no need for the expensive sculpture which is necessary with large pulpits. A crucifix and some delicate ornament in relief are introduced, but without them the pulpit would still be pleasing from its general form, and might be acquired for poorer churches. Messrs. CARPENTER & INGELOW, in their Tower and ante-Chapel at Hurstpierpoint, and Chapel at Abbots Bromley, are faithful to the traditions of the office, which are all in favour of extreme quietness and fidelity to precedent. In his St. Columba, Wanstead, Staffs, it is evident Mr. E. PRIOLEAU WARREN was compelled to deal with the problem of cheap churches and successfully. No doubt the interior is plain and the brick is not concealed in the chancel, but the forms are always satisfactory. The utilisation of one of the tie-beams of the roof to support a crucifix is in keeping with the general endeavour to respect tradition and economy at the same time, and to excite reverential feelings without much cost to the congregation.

Mr. JACKSON, A.R.A., has two views of the chapel and cloisters for St. Peter's College, Radley. The style is vigorous and truly Gothic in spirit, but without any indication of that mechanical reproduction of parts of certain Mediæval buildings which has helped to bring the style into disrepute. The view of the spire of St. Mary the Virgin at Oxford, is as convincing as Mr. JACKSON's letters about the groundlessness of the allegations of vandalism made by the Society for the Preservation of Ancient Buildings. Sir A. W. BLOMFIELD's Chapel, Selwyn College, Cambridge, has a window of a kind for which there are not many precedents; at the sides where one expects openings is solid masonry. St. Augustine's Church, Tonge Moor, by Mr. FREEMAN, looks on the drawing as if light was excluded; it also has a screen. Mr. JOHN BIGG has a careful exercise in design—a chapter-house in red brick. Mr. KEMPSON's St. Peter's, Pentre, seems to be rather clumsy in form; it has a square tower, and a small belfry breaks the long line of roofing. A small porch to Higham Church appears on a drawing by Mr. BERRY. St. Matthew's Church, Morningside, Edinburgh, by Mr. BLANC, suggests that the Pointed style signifies having sharp-pointed, piercing parts, which would be fatal to any birds that might alight on them. The drawing at first excites surprise, but the absence of vigour in the building soon becomes too apparent. Mr. PONTING's chancel aisle to Donhead St. Andrew's Church is low, with a battlemented cornice and stout buttresses, altogether superior to the nave. The interior of the Eglise Protestante in Soho Square is represented in Mr. ASTON WEBB's drawing, and from the benches to the roof we can see evidence of a desire to bring all parts into unity. For his church at Huyton Mr. CARÖE has preferred narrow lancet windows, and therefore could not adopt the free Perpendicular, with its breadth of window-openings, which is now in vogue.

The design for the cathedral at Victoria, British Columbia, by Mr. H. WILSON, is very bold and unconventional, but on that account it was probably considered as too difficult for any of the local builders to undertake. The west front of the Lucknow Cathedral, by Mr. W. EMERSON, is Gothic that appears to have a remote relationship to one of the numerous Indian varieties of building. Instead of a spire there are two towers, and a rose window is introduced over the entrance, the composition being on the whole attractive. The new town church, by Mr. LEONARD STOKES, is worth the attention of the clergy, for, although the exterior is impressive, there is an absence of the parts that are often oppressive by their cost.

According to VOLTAIRE, there is not much use in having VITRUVIUSES in a country unless there are also AUGUSTUSES to give them commissions ("c'est peu d'avoir des VITRUVES, il faut que les AUGUSTES les emploient"). In England Imperial works are so rare they may be reckoned as outside ordinary practice, but a new VITRUVIUS (assuming he could design as well as legislate about building) need not be afraid to venture among us, for plain citizens are ready occasionally to expend as much on a dwelling as a Roman emperor on a public building. That Domestic architecture still flourishes in England, in spite of financial embarrassments, is manifest from what is seen in the Architectural Room, for the majority of the drawings are views of houses—we might even say country-houses. It is among them also that we can find more traces of the influence of old English building than in the examples belonging to other sections. There is enough to demonstrate that Queen Anne, although less prominent in public than formerly, has not abdicated, and here and there something foreign may be discerned, but there can be little doubt that this year the old stately houses in masonry or brick, which are now accepted as examples of English Renaissance, and the developments of the English cottage which are known as half-timbered houses, were the sources from which most inspiration has been drawn. There is consequently more or less resemblance between many of the drawings; to point out the differences would need more space than is available, and would not perhaps be worth the labour.

The first in the catalogue is "A doctor's house in the country" (a vague sort of description, which should not be sanctioned), by Mr. E. B. LAMB. The bricks are of a dull muddy colour, and the woodwork is painted grey. The novelty of the combination of colours, we suppose, gained admission for the design rather than its architectural merit. MESSRS. WIMPERIS & ARBER, whose work is associated with Mayfair, in their additions to "Roxley" have adopted country fashions. The proposed house, based on Bramhall Hall, by Mr. R. A. BRIGGS, denotes the hold which the Cheshire district has taken on architects. It must be said the imitation looks rather stiff, and the abundance of quatrefoils hardly seems suitable to an age in which problems in practical geometry are taught in night-schools. The house 194 Queen's Gate, South Kensington, is very differently treated by Mr. BRIGGS. The union of convex and concave curves in the plan of the drawing-room windows is worth trying, and if the rustication appears a little too emphatic, it may be demanded by the character of the neighbouring houses. Mr. SUGDEN's "Woodcroft" may look better in substance than on paper; in the drawing the gables are curiously ungraceful. There is no escape from Ulster, even in the Academy. Mr. F. L. PEARSON has a most un-Irish house from "Lismoyne, near Belfast," for instead of being called a castle and appearing to express that "one only master grasps the whole domain," it is a cheerful English country-house of two storeys, built of red brick and hanging tiles. Another house of the English type at Coleraine is contributed by Mr. F. E. WARD. After seeing them, the Irish village at the World's Fair, Chicago, designed by Mr. L. M'DONNELL, with its castle and cottages (the latter suggesting warmth and comfort of which the peasantry are ignorant), cannot fail to set people thinking about the connection between architecture and the Irish question. The shops in Camden Town, on a corner site, by Mr. E. J. BENNETT, are better than ordinary buildings of the class.

Drawings of the entrance gateway and lodge, Welbeck Abbey, by Mr. JOHN BROCKE, and the entrance gate and

lodge, Eaton Hall, by Mr. R. W. EDIS, are placed together. The piers in the former are the more massive. They bear heraldic supporters, but are without lamps. The Eaton piers, which appear straitened in dimensions beside the others, are surmounted by vases which express nothing, and by lamps which are of use. They would serve as well for the boundary of a suburban building estate, or to mark the approach to a citizen's box at Enfield; the Welbeck gateway would be out of place in any other position. Banacre Edge, Witley, by Mr. B. CHAMPNEYS, is a pleasing example of country-house, the ground floor having bay windows. In Swan Buildings, E.C., a warehouse with a narrow frontage, the brickwork, of which there is little, is arranged herring-bone wise, and gives some variety to the building. "Compton Leigh," Hampstead, by Mr. NEALE, has an odd effect, as there is no visible means of ingress or egress except the windows. Mr. G. KENYON, in his small country-house, Yorks, has skilfully avoided monotony in planning. Mr. NEVE's "Goddington" is in the Cheshire style.

MESSRS. ERNEST GEORGE & PETO's drawings are among the earliest which are sought in each year's exhibition. The house in Delahay Street is T-shaped on plan, and in the angle a sort of turret is introduced. "Motcombe" is a large mansion of old English style. "West Dean, Chichester," is an interior showing a chimney-breast of solid masonry with pilasters (china maniacs may regret to see so fine an opportunity for the display of treasures wasted); the walls are panelled and there is a gallery. The "Villa" was designed for the Gaekwar of BARODA, and forms a most picturesque group with its open corridors, verandahs and dining pavilion. In Mr. G. C. HORSLEY's design for a country-house good use has been made of figure decoration, as there are panels of the seasons between the upper windows, and the gables are adorned in a similar style. Mr. UNSWORTH shows a long low house, partly with framed work, "Ashcroft." MESSRS. JAMES BROOKS & SON, instead of church work contribute a view of the South-Eastern Hotel, Deal, in which terra-cotta is ably utilised. Near it are houses by MESSRS. COX & COOKSEY, R. C. MURRAY, DAWBER, J. CLARKE, DOUGLAS & FORDHAM. Mr. ELY's "Entrance to Ashby Folville" might be mistaken for a view of old work. MESSRS. BEESTON & BURMESTER have four drawings of two important country-houses, which are handled in masterly style. There are also houses by MESSRS. JACKSON, A.R.A., W. T. WALKER, KIDNER & BERRY, HART, CARÖE, MITCHELL, B. SMITH, W. A. PITE, DYBALL, WORNUM, A. C. BLOMFIELD, STEVENSON, WATSON, GRAYSON & OULD, WILLINK & THICKNESSE, CUTLER, FLOCKHART, INCE, WILLOCK.

The most important of the hospital buildings is the New General Hospital, Birmingham, by Mr. W. HENMAN. That such a group will be an ornament to Birmingham is unquestionable, and it is to be hoped that there will have to be no sacrifice of any part. The London notion of stateliness is in such buildings happily avoided, for there is no flight of steps to torture "accidents" who are carried up them. The Royal Infirmary, by MESSRS. YOUNG & HALL, is also of an advanced character, for it resembles a group of agreeable country-houses. In St. Mary's Hospital, Paddington, MESSRS. SALTER & ADAMS have endeavoured to avoid the dismal appearance of so many London hospitals. The Seamen's Almshouses, Cowes, by MESSRS. CLARKE & MICKLETHWAITE, does not probably look as dreary as the drawing of a part suggests.

The examples of decoration are not numerous. Mr. AITCHISON, A.R.A., has only a part of a smoking-room, which suggests coolness and cleanliness by its whiteness. The aim of Mr. TEMPLE in his "Bath-Room," where tiles, mosaic and faïence are used, is excellent. The conventionalised plants would have a good effect, but the figure-panels would need to be in better style than is indicated. Mr. G. C. HORSLEY, in his design for the painted decoration of the roof of an university hall, introduces figures that are emblematic of the sciences. A river runs at their feet, and palm trees separate them. The designer suggests the manner of early Italian painters, which, it is needless to say, is refined and appropriate for such work. Mr. GWATKINS's designs for friezes are remarkable for their bold conventionalising of leaves. Mr. E. W. DAVIES's "Conflict" is a frieze in which athletes struggle with pythons on the ground. Mr. WESTLAKE's "Holy Women," part of a frieze,

is very careful, but the drapery seems to be derived from early German wood-carvings. Among the windows is one for Lowestoft by Messrs. HEATON, BUTLER & BAYNE, which is a model of skilful arrangement.

THE FUTURE OF ART.

IN his speech at the banquet of the Royal Academy the President said:—

The counting of graves is at all times an unwelcome and a painful task. Especially is it so on an occasion of which it is one object at least to honour the achievements of the living. It is, however, a task which loyalty to the memory of those who were themselves amongst the living when last we met lays imperatively upon the occupant of this chair, and from which those kindly references of the Prince of Wales in the earlier part of the evening do not absolve me. Within that period death has closed the record of three of the members of our body. The first to pass away was a sculptor of great and wide repute, whose hand made lasting in marble or in bronze the bodily image of not few of the most conspicuous Englishmen of his day—a man of high culture, whose active mind was not satisfied with one form only of outward energy, and seeking expression with the pen as well as with the chisel has attached to graceful poems the name of Thomas Woolner. After this votary of form, an artist was snatched from his many friends to whom light and colour were as the breath of life, and on whose canvases blaze the rich tones which his eyes had drunk in, no doubt, in the land of his birth—a land where brown streams are laced with gold, amid the heather's purple frame—for a Scot among Scotsmen was our lost friend Pettie. Last—but the other day, indeed—English landscape-painting lost in Vicat Cole one of its most conspicuous names. Typically English were the scenes on which he loved to dwell; the coppice, the glade, the rolling pasture fading from green to distant blue, summer slumbering on brown-tipped corn. But most of all our English Thames had won his heart and occupied his hands; he had followed its stream with faithful brush throughout its length, from where its first sweet gurgle is heard within the grass to where far away, salt and sullied, it rocks on turbid tides the carriers of the commerce of the world. By these three names, then, our art is poorer to-day. Meanwhile, as one generation fades away another presses forward to stand where it stood; the torch passes on from hand to hand, and those who, casting their gaze into the future, are keenly concerned to divine what shape that future will take and what rank it will hold, may see beyond doubt signs of much, if sometimes wayward and unchastened, vigour among the generation that is pressing to the front. And let me note in passing the legitimate gratification felt this year by our body, a body whose first function and duty lies in the training of the young, in view of the number of works of merit, both in sculpture and in painting, due to the hands of youths who either are still, or were but recently, among the enrolled students of the Royal Academy. But, gentlemen, looking from a wider standpoint at this exhibition, of which, it seems to me, the most carping critic could not challenge the comprehensive catholicity, and embracing further in the field of vision the many and manifold exhibitions, especially of painting, which each season brings forth, struck as all must be deeply with the vehement and almost feverish strife of conflicting theories and opinions which is rife about us, it is impossible not to feel strongly how perplexing such a condition of things must be to the very young, who, on the outer threshold of their career, eager and still malleable, seek a sure path in such a labyrinth of contradictions. Extreme youth when it is healthy is bold and fearless, and not a little inclined to rebel against tradition, however rooted in the long assent of men. And here, gentlemen, I would not be misunderstood. Steeped as I am to my inmost marrow in reverence for the mighty men of the past to whom art owes whatever of true sublimity it boasts, convinced unshakably of the vital validity of the great principles on which their achievements rest, I am yet not of those who would refuse to art all power of evolution, or who believe that, though assuredly it will never reach more lofty summits, it may not send forth lateral shoots fresh and delightful as only they are, indeed, nourished from the strong sap of the parent stem. In brief, I do not believe—to change the metaphor—that they who, in our time, have wedded their lives to art have clasped to their breasts a lovely but a lifeless corpse. To the very young, then, I would fain offer one or two matters for thought, if, perchance, they will hearken to one who has grown old in unwavering sympathy with their struggles and their doubts. I would beg them to keep ever before their eyes the vital truth that sincerity is the well-spring of all lasting achievement, and that no good thing ever took root in untruth or in self-deception. I would urge them to remember that if every excellent work is stamped with the personality of its author, no work can be enduring that is stamped with a bor-

rowed stamp, and that, therefore, their first duty is to see that the thoughts, the emotions, the impressions they fix on the canvas are in very truth their own thoughts, their own emotions, their own spontaneous impressions, and not those of others; for work that does not spring from the heart has no roots, and will of a certainty wither and perish. This other maxim also I would urge on them—that true genius knows no hurry, that patience is of its essence and thoroughness its constant mark; and, lastly, I would ask them to believe that the gathered experience of past ages is a precious heritage and not an irksome load, and that nothing will better fortify them for future and free development than the reverent and the loving study of the past.

RENAISSANCE AND GOTHIC ART.

THE prizes won during the past year by the students of the Nottingham Art School (which is directed by Mr. J. Harrison under the Corporation) were handed to them by Mr. Wyke Bayliss. In his address he said that in art, as in everything else, the chief question was, How was excellence to be attained? And when they thought of the great contests going on, not only there, but throughout the country in those schools of art, it was well sometimes for them to get away for a moment from themselves, to forget their narrow circle and to think of the larger arena and greater men in the long history of art in this world. Men engaged in art had been always striving for a prize—the prize of immortality, the prize of being leaders in the great army of art. They knew that the world had seen before their time two great periods of art—the Greek and the great schools of painting of Italy. He would not go so far back as to the records of Greece, but he would just for a moment ask them to think of one or two things in relation to the great school of painting that existed in the fifteenth and sixteenth centuries. He supposed there were none of them but would remember amongst all the splendid names that made Italian painting glorious, five names in particular that seemed glorious beyond the others. He would name them. There was Michel Angelo, there were Titian, Correggio and Leonardo da Vinci. He had named four; did they think he had forgotten the fifth, Raphael? There were other great painters, but those were supreme, and why? Michel Angelo was supreme, not because he was versatile, architect, poet, sculptor, painter; Michel Angelo was eternally supreme because he was supreme in one of the great elements of art, imagination. He had not time to tell them in detail—they probably knew all this, but what he wanted to do was to put these two or three things together, that they might think of them in relation to their own work. Michel Angelo was supreme in imagination and Titian was supreme as a colourist, as a master of the splendour of colour. Correggio was supreme because he was a master of the expression of the tenderness of womanhood and child-life, and Leonardo da Vinci was supreme because he was a master-scholar, an expert, the most learned painter that the world knew. Where was Raphael? Raphael was the equal of Michel Angelo in imagination, he was the equal of Titian, or not inferior in colour; he was as graceful as Correggio, as accomplished as Leonardo da Vinci—he was, in a word, an all-round man. And here was the great point for all to consider who had to carry out a great purpose in life. Let them aim to be perfect in one thing. Other things would come with it. They could do the work before them, and in doing it they would qualify themselves for doing greater work. He had named these men because their names were dear to them and stirred their hearts. They were painters pure and simple, and, speaking as an artist, and making art the purpose of his life, he had named these men to them, not with a view of persuading them to be amateur artists—that was not the purpose of these great schools of art. The great purpose of such schools was for them to do something specific, something definite, something that should be applied to decoration, something that should make their homes beautiful, and that should make their manufactures the glory of the world; and in doing that from amongst them the artists would come, because Englishmen were a race of artists. He asked them not to believe the abominable pessimism that was preached and taught in the supercilious press. Englishmen were a race of artists, and ought to do in art great things. Even though he would not weary them with a long discourse, he would just say a word in justification of the statement. The world, as he had said, had seen two great schools of art, the Greek and the Italian. But was there not another? Had there not been another creation of art, which stood side by side with the Greek? Did not Westminster Abbey, Lincoln Cathedral and Salisbury Cathedral, and the other splendid cathedrals of the country teach them something? Were not the magnificent Gothic buildings, the poems in stone, which made this land lovely, as beautiful, as splendid, as noble in art, as a Greek temple? They were, and he said this not merely to those who were present on that occasion, but always, and everywhere,

that the great period of Gothic art was as true, as great, as splendid a creation of art as the world had ever seen. What was the Gothic art, what were the Gothic splendours of their cathedrals?—English, English pure. As much as the name of the Parthenon was that of a Doric Greek temple, so the very name of its architecture was Early English. Greek art lived once and died, and never came to life again; but English art had lived and come to life again. What was the leading, what was the creative force which had made landscape art a glory in the world, but the work of English painters, such as Constable and Turner? And the painting of God's work in nature was as splendid as the painting of God's work in man. Not only in the splendour of landscape art, but even in the use of a material, what had the English done? They had created the art of the modern world—water-colour. So that he said they were a race of artists, and a splendid career was before them. What art could do for a nation was without limit in the splendour of its results. There was one condition only, and it was that the harp, the music, the art should be true, and it was for their schools of art to work out the truth that should awaken and strengthen and glorify the nation.

PUBLIC IMPROVEMENTS IN YORK.

THE following report, addressed to Mr. A. Creer, engineer has been forwarded to the Estates Committee of the York City Council. It is by Mr. Alfred Waterhouse, R.A. :—

In accordance with the request contained in your letter, that I should give the Corporation of York my professional opinion as to the best treatment of the vacant land at the corner of Blake Street and Duncombe Place, I, on Wednesday last, the 12th inst. (April), met the Estates Committee, and visited the site in question both before I met the committee and in their company.

I may say that it at once appeared obvious that nothing should be erected on the vacant site in any way to block out more of the view of the Minster from the corner of Museum Street and Blake Street than is blocked out by the Probate Registry Office at present. This would involve any new building on the site in question being kept behind a line drawn between the aforesaid street corner and the north corner of the Registry Office, and this restriction I understand to have been already insisted upon by the Little Blake Street commissioners. I would, however, go further than this, and restrict the height of any new buildings on this site—(1) to the height of the Registry Office, so far as they cover the site of 458 square yards on plan "A" accompanying report of Estates Committee to Council on November 9, 1892; and (2) if the new buildings were to be extended in a north-westerly direction towards the street, that then such extension should not rise above a line drawn from 5 feet above the pavement at the corner of Blake Street and Museum Street to the ridge of the Registry Offices. This restriction, which I would enforce, to prevent new buildings being obtrusively high near the corner of Blake Street, and so dwarfing the appearance of the Minster when it first comes into near view, is all that seems necessary on approaching from the railway station.

When, however, the question is considered from Blake Street, it assumes a very different complexion. The aspect of the Minster is so imposing from this point that I should suggest that no further obstruction should be put on the ground than is at present created by the Registry Office. In other words, that the north-west front of any future buildings should not project further than shown on plan "A" aforesaid. Even building on that restricted site would shut out the beautiful peep of the south transept now obtained behind the Registry Office.

In order to get an unobstructed view of the west front, the nave, central tower and upper part of the south transept, giving an architectural group perhaps unsurpassed in the world, the new Registry Office should, in my opinion, be removed, and its site, together with that now unoccupied at the corner of Blake Street, left entirely free from buildings.

I was able to get on the roof of the Assembly Rooms opposite the centre of unoccupied site, but not on to the higher roof adjoining. One would get from thence a very good notion of the general view of the Minster from the street below, and it might possibly be worth while having a photograph taken from thence.

To recapitulate :—(a) If the view of the Minster from Museum Street is only considered, then the line of the Little Blake Street Commissioners seems to me the right building line, the building to assume some such an outline as I have sketched, and to be restricted in height as I have before suggested. (b) It is, however, very desirable in my opinion to preserve as much of the view of the Minster as possible from Blake Street. This could best be done, the Registry Office buildings being where they are, by confining the new buildings to the site outlined on the plan "A" accompanying Estates Committee's report. (c) But I should strongly urge the Corporation

to consider the advisability of removing the Registry Office to another site, and not covering any of the ground at the corner of Blake Street and Duncombe Place, so as to open out the Minster more completely from Blake Street, and so secure a unique view of the noble building which must always remain the architectural glory of your city.

ARLES AND NIMES.

AT the last meeting of the Eastbourne Natural History Society, Dr. Habgood read a paper entitled "A Visit to Arles and Nimes, with special reference to the Archæology of the Neighbourhood." The lecturer gave a short sketch of the occupation of that part of France, embracing a period of from B.C. 154 to the fall of the Roman Empire in the fifth century. Arles was called "the Rome of Gaul," and on the fall of the Roman Empire became the capital of the kingdom of Arles. It is now a small town. Its antiquities are chiefly Roman, though many early Christian churches, now dismantled, are to be seen and in use as store-houses, shops and granaries. The theatre was seated for 10,000 spectators, and followed the Greek model in design, consisting of a semicircular part which contained the audience, and was filled with concentric seats ascending from the centre to the outside. The floor was semicircular, and was called the orchestra. The opposite or oblong part contained the actors; and within this was erected, in front of the audience, a wall, ornamented with columns and sculpture, called the scena. Only two of these columns are now standing, and they are of the Corinthian order. This building was elaborately decorated, and is said to have been demolished by the early Christian bishops, who regarded it as a focus of vice and idolatry. The amphitheatre, once capable of seating 25,000 people, is more damaged by human hands than by time. It differs from the theatre in being a completely circular building filled on all sides with ascending seats for spectators, and leaving the central space, the arena, for fights and public shows. It dates from B.C. 43. Three square watch-towers, added by the Saracens in the eighth century, still remain. The building was used at that time as a fortress. The cathedral church of St. Trophimus is celebrated for its twelfth-century doorway, which is decorated with figures of St. Trophimus, St. Stephen and the twelve Apostles. St. Trophimus first introduced Christianity into France.

The interior, which is mainly eleventh-century work, is bare and a striking contrast to its highly-decorated façade. The ancient cemetery, dating quite eighteen centuries ago, is of vast extent, and was originally divided into two parts, one for the Pagans and the other for the Christians. The ground teems with empty stone coffins and monuments, though the best have long since been removed to museums. A considerable portion of the cemetery is now used as a promenade, the coffins being neatly arranged on each side. Another portion is still in use as a modern burial-ground, the remainder being covered with railway workshops. Many chapels originally existed in this cemetery; the most curious, that of St. Honoratus, still remains and contains many empty coffins and heaps of human bones. About two miles from Arles is situated the Abbey of Mont Majeure, built in the eleventh century and well worthy a visit. Nimes was described as being about sixty-two miles north-west from Marseilles, and a clean and lively place—a great contrast to Arles in that respect. It is surrounded by open boulevards and is richer in well-preserved antiquities than any town in France. The Roman amphitheatre is 502 feet in diameter and 70 feet high. It is seated for 30,000 people, and is much better preserved than the Coliseum at Rome or the amphitheatre at Arles. Of date unknown, it is yet the most perfect example of its kind in the world. It consists of two arcades with sixty openings, between which are three-quarter columns with ornamental capitals supporting a continuous entablature. The Visigoths converted it into a fortress, and the Saracens used it as such in the eighth century. Down to the middle of the eighteenth century it was filled with mean hovels, all of which are now swept away. Fêtes and bull-fights are still held in it. The temple of Caius and Lucius, vulgarly called the "Maison Carrée," was built A.D. 4. It is a Corinthian temple and one of the most perfect and beautiful relics of Roman art in existence. Excavations made in 1822 prove it to be but the sanctuary of some great building, probably the forum of ancient Nimes. No building in Europe is valued more highly as a gem of ancient art than this interesting building. The grand vestibule supplied the original for the portico of St. Martin's-in-the-Fields and the Royal Exchange, London. The building has had a curious career. First it was a temple of the gods, then a Christian church, then the Town Hall of Nimes, a stable, a mausoleum, attached to a convent, and finally a museum of Roman and early Christian tombs, monuments and other relics. In building it the Romans followed somewhat closely the design of the temple of Minerva at Athens, substituting their favourite Corinthian columns for the Doric order of the Greeks. The lecturer also referred to the Roman gateway, the Roman baths

the Tourmagne, thought by some antiquarians to be a dismantled tomb, the cathedral church of St. Castor and the church of St. Paul. The paper was illustrated with diagrams and original views.

SYMBOLISM IN ART.

IN his third lecture on "Symbolism in Ceremonies, Customs and Art," delivered at the Royal Institution, Mr. John Macdonell, LL.D., said that in ethnological investigations there had been too great a tendency to overrate the purely intellectual significance of ceremonies, and to overlook their secondary value as excitements to emotion. The love of ceremonial for itself is enough to account for the continuance of many of them. The initiatory rites of the Australian and North-American Indians, whatever their origin, existed mainly to gratify the love of mystery and the delight in ritual for ritual's sake. Many burial customs with very different origins were now really pungent emotional stimulants. The secret of the persistence of the Greek mysteries was not the doctrine taught therein, for Lobeck had shown there was in effect none; the pageant and the festival were sufficient in themselves. Dancing, too, as Lucian's dialogue showed, had been a great element in ceremonial, grave no less than gay. It was a law of rites and ceremonies that, even if the form remained the same, the meaning changed—which the lecturer illustrated by references to sacrificial usages. Selden had spoken of ceremonies as cups or vessels for preserving principles, and the contents of the vessels varied from one generation to another. The lecturer, passing to symbolism in art, referred to idols as symbols beyond all others. In many cases so far was beauty from being essential to them that additional significance seemed to be given to them by positive uncouthness. Probably no masterpiece of a great artist had ever become associated with miraculous powers. Not the Sistine Madonna, but some poorly-executed picture has gathered about it the affection of the multitude. The lecturer described the symbolism in the art of the Middle Ages as the key to much of what was found in the "Bestiaries" or compilations describing the moral significance of different animals. The proneness to symbolism in the best minds of the Middle Ages was in some degree due to the imperfect state of music, the modern outlet for feelings which once turned into mysticism. Something in men was for the first time satisfied by the Masses of Palestrina. What significance in the fact that the ancient world, with its rudimentary homophonic music, was almost tuneless. What more momentous event than the fiat, after the jarring discords of the Middle Ages, "Let there be harmony." In spite of its formal symbolism Christian art had its triumphs, some of them too little known. Folded within the leaves of missals, psalters and gospels was in the illuminations a world of miniature pictures of ineffable delicacy, the work of men of like mind with those who raised the great Gothic cathedrals of Europe. Were it possible to gather these scattered treasures together there would be a universal exclamation of delight. The great artists of the Renaissance did not eschew symbolism. In Michel Angelo's decoration of the ceiling of the Sistine Chapel with its vast symbolism was unfolded a theory of history as comprehensive as any to be found before Bossuet's "Universal History." In the hands of inferior artists symbolism became insipid and tedious. The over-ingenious designs of Ripa and Alciat, once popular and esteemed, discouraged invention. In music there was a symbolical element—a larger element than in any other art, and an increasing one. Some artists would be, in spite of all canons to the contrary, thinkers, and would turn to symbolism. An intolerant application of the maxim, "Art for art's sake," would give, not the Greek art of Phidias, but the pseudo-Greek art of the boulevard. Where did symbolism begin and end? Just where the mystery of life began and ended.

TESSERÆ.

Miniature Painting.

IN tracing the origin of miniature painting, we are carried back to the earliest periods in which art in any form was known. For we are told that the ancient Egyptians were in the habit of adorning their papyri with miniature paintings of hieroglyphics, and Pliny tells us that a similar art was practised in the early days of Greece and Rome. And that it was still existing in the earlier periods of the Christian era is evidenced by the fact that there are still preserved two specimens at least of manuscript illuminations, probably of the fourth or fifth century—a fragment of a Virgil (which, although a fragment, contains fifty miniatures) in the Vatican, and a portion of a copy of Homer in the Ambrosian Library at Milan. But it was in the Middle Ages, from the eighth to the end of the fourteenth century, that this art reached its perfect development; for during that period, in nearly all the religious houses, the monks spent much time in its careful study, and in

the patient labour of illuminating their manuscripts of the sacred volumes and copies of the works of the classical authors. They were called illuminatori, and from the fact that the initial letter of a chapter or a paragraph was painted in red, the pigment for which was the Latin minium, or red lead, they acquired the name of miniatori, from which our word miniature is formed. Curiously enough, therefore, this word, which always conveys now the idea of smallness or minuteness, and which we have adopted as an adjective also to express the same idea, comes directly from a word which did not in any way indicate the size of the picture, but only the colour of the initial letter, which, with its ornamentation, furnished the border or frame in which the picture was set. It would be impossible to say too much in praise of the work of these "miniatori" of the Middle Ages. All over Europe, in Italy, France, Germany, the Low Countries, Spain and England, this beautiful art was assiduously studied and with wonderful results, and those who have seen the superb examples preserved in many collections of the manuscript illuminations of these old artists find it difficult to say in what country the finest were produced. And it is impossible to over-estimate, too, the value of this work in preserving and supplying valuable material for the development of the art of painting throughout the world. These little paintings, the result of earnest thought and patient, painstaking care in the cloister and the cell, furnished the "studies" for those great masterpieces on panel, on wall, and on canvas, which mark a golden age in the art of painting. With the invention of printing, miniature painting, in the form it had thus far taken, practically disappeared, and in modern times it has been confined almost entirely to the production of portraits. In this direction, too, it has played an important part in the history of art by teaching faithful accuracy of drawing and delicacy of expression, and serving at the same time more than any other department of painting to produce and preserve a succession of portraits more or less faithful of men and women noted in history.

The Sheltering of the Roman People.

According to the calculations of De la Malle and others the area of ancient Rome was five square miles and sixty-three acres. It seems hardly possible to estimate, on a comparison of the mode of life and social demands of the ancient Romans with those of populations nearer our own era, the numbers which might have been accommodated, according to the fashion of the time, within that area. We must make an allowance, no doubt, for the ordinary habits of outdoor life among the Romans, vast numbers of whom may be said to have dwelt in the circus, the theatre and the baths, and only to have slept in the miserable dark cabins they called their homes. It may be believed that during part at least of the year multitudes of the lowest class even slept in the open air, or under the shelter of colonnades, as in Naples. We are sometimes told indeed to look to this modern city for an example of the conditions of life in ancient Rome. But though at the present day the temperature of Rome is said to suffer less violent extremes than other places in Italy, the well-known passages in Horace, Livy and Dionysius do not allow us to question the great severity of the winter there in ancient times. Great allowance, however, is unquestionably to be made for the treatment of domestic slaves, who were huddled, we may believe, without reference to their comfort, or even their health, in the holes and corners of their masters' houses, often confined at night in the basements or vaults of the mansion, and particularly of the temples and public buildings. The vaults of a public building might hold a vast number of public slaves, but it may be questioned whether the service of the temples and basilicas of Rome required the attendance of so great a multitude. Indeed, the question of this density of inhabitation turns very much upon the numbers of the slave population—a problem of which no reliable solution has yet been found, and which the most careful of modern inquirers, M. Wallon, has prudently abstained from attempting. Some inquirers divide the population equally between the servile and the free, though all inclining apparently to a still higher ratio of slaves. Other writers, however, would reduce the proportion very much lower, and it would be difficult certainly to point to any known example of domestic slavery at all approaching to this extent. Generally, the Roman citizen, being himself fed almost gratuitously by the government, must have felt more sensibly than the modern the burden of servile mouths to be supplied at his own private expense.

Italian Renaissance.

Had the Renaissance of Italy died out on the introduction of the full-grown Italian style in the fifteenth century, it is probable neither our Elizabethan, nor the French or Spanish Renaissance styles would have existed, and that the various western nations must either have adhered to their respective Gothics or have taken at once to the full Italian. These offshoots of the Italian Renaissance stand at different distances behind the parent style in classic purity and grace of form and harmony of decoration, as well as in consistency and truth,

through the antique being less understood and felt in the north and west than in Italy, where the Gothic had not, nor could have, the powerful influence it had on this side of the Alps, or so strongly infuse itself into the current style. Indeed, in Italy there was no Gothic, properly so-called, so to infuse itself, the Italian Gothic, especially that of Venice, having little of the essential, aspiring spirit of the northern styles. In each country, too, what was derived from the Italian was greatly modified by peculiar national feeling, as well as by artistic disability and inferiority of resource. As the same seed falling on different soils must produce different fruit, so these Renaissance styles, though they had their source in the same parent style of Italy, soon widely diverged and became very dissimilar phases of art. Generally each showed the same predilections as regards form and proportions, as well as decoration, which had been exhibited by its Gothic predecessor, of which, at first, it was merely a reproduction in a new and classic dress.

Leonardo Da Vinci.

Leonardo's powers were too much for one man, or for one ordinary length of life; they trod on each other. With fewer gifts there would have been more results; with less ardour for science, more performance of art. His temperament also impeded his free course. He was fastidious, dreamy, impulsive, procrastinating and ambitious of shining in society. He saw before him summits of perfection higher than mind or hand could attain. He left what was good and certain for experiments after what he felt would be better. He studied everything in turn with utmost ardour, and he finished nothing he undertook. All people courted him, all crafts tempted him. Even in his art he was pulled in opposite directions—indeed, in all directions. His idea of our Lord's head is the loftiest that art has realised. His Apostles' heads are among the truest and noblest transcripts of nature. He attained in the countenances of his Madonnas and children an ineffable sweetness and pathos which breathe the very airs of heaven. At the same time he analysed the principles of all that is monstrous and misshapen in the human face, and in his caricatures, of the authenticity of which there is unhappily no doubt, he seems to have gloated over forms of wanton hideousness, half-human, half-brute, and all traced with an exquisite line from which we turn with repugnance. The temperament of Leonardo may be recognised by the very processes of his art. He altered and retouched without ceasing. His chief aim seems to have been not so much to complete a work as to retain the power of correcting and improving it. Thus he added coat to coat and film to film, ever deferring the end of his labours till a greater solidity and body of colour (*impasto*) gradually grew beneath his hand than any other painter before him has left. "Leonardo's refined taste and fastidious habits," says Sir Charles Eastlake, "may be traced in opposite effects, in untiring labour and causeless dissatisfaction." The wonder is not that he left so little, but that under the circumstances he should have left enough to establish the transcendent nature of his art. Indeed, there is nothing stranger in history than the fact of so great a reputation resting on so shattered and uncertain a basis, on one single work long reduced to a shadow, on at the most half a dozen pictures, for which, or for parts of which, his hand is alternately claimed and denied, and on unfinished fragments which he himself condemned. He was, properly speaking, the founder of the Italian process of oil-painting, but, the sacrifices he made to establish that process, however obvious to those who study him, can never be entirely computed. His very experiments on the nature of oil and varnishes can only be considered as misuse of precious time, and misapplication of an unrivalled hand. His observation of external nature and of her more hidden laws and forces was equally close, ardent and original. His social gifts and worldly qualities were irresistible, while as to the higher springs of action he seems to have been morally indifferent as to whether he talked and laughed, played and sang, painted and modelled, designed engines for the benefit of all time or invented toys for the amusement of an evening in the service of friend or foe, compatriot or foreigner. Of few men could so much that is psychologically interesting be said, and of few men of note is so little known.

Early Academies in England.

The earliest institution of a public character, a part of the plan of which was instruction in the arts of design, was the Museum Minervæ, established by Charles I. in 1635, the eleventh year of his reign, in the house of its first regent, Sir Francis Kingston, in Covent Garden. Walpole gives a slight account of it in the "Anecdotes of Painting," in the notice of Sir Balthazar Gerbier. The patent of its erection is still extant in the Office of the Rolls, and the rules, orders and plan of the establishment were printed in 1636, to which is prefixed a coat-of-arms granted to the regent and professors of the academy in 1635. It gave instruction in the arts, sciences and languages, in fortification, and even in riding; but none except such as could prove themselves to be gentlemen (that is, in position)

were admitted to study in it, in imitation probably of the exclusive law in force among the ancient Greeks after the time of Pamphilus, of Amphipolis, who established the famous school of Sicyon, which was that none but the free-born, or what is equivalent to it, the noble, should be allowed to practise the arts of design in Greece. As might be expected, the Museum Minervæ did not survive the Revolution. Previous to its establishment, says Walpole, a committee had been appointed in the House of Lords, of which the Duke of Buckingham was a member, for taking into consideration the state of the public schools and method of education. What progress it made is not known, but the Museum Minervæ, for gentlemen, was probably a part of its fruits; and with such a specimen of its liberality in the education of the public, we have no occasion to regret the suspension of the function of this committee. Sir Balthazar Gerbier established an academy of his own in 1648 upon similar principles at Bethnal Green, which he called "The Academy for Foreign Languages and all Noble Sciences and Exercises." Walpole mentions also an Academy of Painters, of which Sir Godfrey Kneller was the head, and at which Vertue, the engraver, studied in 1711. In 1724 another academy was opened in Covent Garden by Sir James Thornhill, which, however, did not rise above the rank of a private establishment. Sir James had before attempted, through Lord Halifax, to obtain the foundation of a Royal Academy of Painting, &c., but in vain. He had even designed a plan, and made an estimate of the expenses of a building suited for the purpose, and containing also apartments for the professors. His estimate amounted to 3,139*l*. In the year 1758 the Duke of Richmond opened a gallery of casts from the antique in Whitehall, forming an academy or gratuitous school of design for young artists, and he established premiums for the best design. This school was under the management of Cipriani for drawing and Wilton for sculpture or modelling, but, like its predecessors, its existence was of short duration, and its ultimate effect was in proportion, though probably to many young artists individually it was of considerable benefit. An advertisement notifying the opening of this gallery "for the use of those who study painting, sculpture and engraving" appeared in the *Chronicle* of February 25, 1758. Youths under the age of twelve were not admitted.

Saracenic Architecture.

The Saracen builders do not seem to have been possessed with an architectural idea; the leading consideration with them seems to have been not form but decoration. For the details of the decoration it is impossible to feel too much admiration. They are skilfully conceived and worked out with remarkable patience, honesty and artistic feeling. But the form, of which they are the clothing, seems too often to want purpose. There is a curious indefiniteness about the mosques, a want of crown and summit, which set them on a much lower level than the finest of our Gothic cathedrals. It is perhaps unfair to judge of them in their more or less ruinous state; yet their present picturesque decay is probably more effective than was the sumptuous gorgeousness of their colours and ornament when new. The want of bold relief in the ornament is one of the most salient defects to us of the north; the surfaces of the mosque exteriors will be found flat and monotonous. The disregard of symmetry is another very trying defect to the eyes trained in other schools of architecture; the windows, minarets, &c., are scattered with no sense of balance, and the dome, instead of crowning the whole edifice, covers a tomb at the side of the building, and thus infallibly gives it a lopsided aspect. It is chiefly to the grace of their minarets, the beauty of their internal decoration and the soft effects of the Egyptian atmosphere upon the yellowish stone of which they are built, that the mosques of Cairo owe their peculiar and indestructible charm. A charm they have undoubtedly, which is apparent and fascinating to most beholders; but it is due to tone and air, to association, to delicacy and ingenuity of detail, and not to the architectural form. Franz Pasha, the architect to the Khedive's Government, himself a fervent admirer of what is really excellent in Saracenic art, has the following criticism on the architecture:—While bestowing their full meed of praise on the wonderfully rich ornamentation and other details of Arabian architecture, one cannot help feeling that the style fails to give entire æsthetic satisfaction. Want of symmetry of plan, poverty of articulation, insufficiency of plastic decoration and an incongruous mingling of wood and stone are the imperfections which strike most northern critics. The architects, in fact, bestowed the whole of their attention on the decoration of surfaces, and down to the present day the Arabian artists have always displayed far greater ability in designing the most complicated ornaments and geometrical figures on plane surfaces than in the treatment and proportioning of masses. Although occasionally difficulties of construction are well overcome, as in the case of the interior of the Bab-en-Nasr, these instances seem rather to be successful experiments than the result of scientific workmanship. The real excellence of the Arabian architects lay in their skill in masking abrupt angles by the use of stalactites or brackets.

NOTES AND COMMENTS.

THE exhibition of paintings and sculpture which will be opened in Berlin, it is anticipated, will possess unusual interest. It will, in fact, be the inauguration of a new era, but whether of long or brief duration remains to be seen. Hitherto the exhibitions in Berlin were restricted to the works of the members of the local academy of art, with the exception of special years, such as 1891, when the exhibitions were international. This year the exhibits will not be drawn from one city or district. The Berlin Union of Artists, as well as the Berlin Academy and the various Düsseldorf unions, will be represented. There has been lately a split amongst the members of the principal Munich society, and the secessionists have resolved to do their utmost to gain success for the Berlin exhibition by contributing their latest works to it. A fine park is attached to the exhibition buildings, which is to be turned to account for supplementary entertainments, for even in cultured Berlin people get tired after gazing on pictures for an hour or two.

ABOUT thirty years ago the members of the Geologists' Association and their friends were entertained at a meeting in Cavendish Square by the dexterity of SIMPSON, or "Flint JACK," who, in the coolest and surest style, converted fragments of flints into arrow-heads with the aid of no other machinery than a small crooked rod of iron. In spite of his antecedents and the geologist's love of the genuine, he made a good deal of money during the evening, for his flint implements and barbed arrows were bought as quickly as he produced them at sixpence a piece. It was a strange scene, which even victims of the fellow's cleverness in turning out prehistoric objects could hardly fail to enjoy. According to a paper read the other night before the Glasgow Archaeological Society by Mr. JAMES NEILSON, that sort of industry, in common with others of a more honest sort, thrives in the North of Ireland. Mr. NEILSON related how, recently, on a visit to the Giant's Causeway, he purchased a number of flint arrow-heads. Everybody seemed to have a large number to dispose of, so he confined himself to a selection. Being rather suspicious, owing to the quantity for sale, he questioned the vendors, and gathered a good deal of information. With the exception of flint flakes and scrapers, he did not see a single genuine specimen. The spurious implements were made to resemble the genuine articles in such a way that it was sometimes impossible for an experienced eye to discover them, and even the best authorities were deceived. Mr. NEILSON believed that the traffic originated by the country people picking up genuine articles in the fields, and these found their way to museums and into the hands of archaeologists. As the demand increased the supply decreased and the prices rose. In this way modern manufacture stepped in and supplied the demand. After inquiry he found out a man who was said to be one of the principal manufacturers of "ancient" flint arrow-heads, and ultimately he succeeded in getting an interview. After conversation he offered to purchase several arrow-heads, but stipulated that they must be made in his presence. It was only after considerable pressure that the Irish Flint JACK consented to make a few arrow-heads, which were exhibited at the meeting. It would be well for collectors if imitative skill did not soar beyond the hazy prehistoric ages. Where is the museum which does not possess spurious antiques? If the original Flint JACK could be credited, specimens of his handiwork were to be seen in the British Museum itself, and as he used to remark with conscious pride, "very good things they were too."

It is proposed to issue next month the first number of a quarterly magazine, which will be entitled *The Illustrated Archaeologist*. The editor will be Mr. J. ROMILLY ALLEN, whose competence is undoubted. As it is intended to avoid subjects which cannot be illustrated, the character of the essays may be imagined. The pages will deal with structures, monuments and portable objects left by man from past ages, ancient arts and industries; the fine arts of antiquity and the Middle Ages, anthropology, and folk-lore as far as the last relates to representable objects. Several antiquaries have promised to give their aid as contributors. Among them are the following architects:—Mr. C. LYNAM, Mr. LOFTUS BROCK, Mr. S. W. WILLIAMS, Mr. J. G. WALLER and Mr. C. B. FOWLER.

IN the last report by Mr. W. L. VERNON, the Government architect for New South Wales, he points out that, although the greater number of the public buildings are in a fair state of repair, yet there are many which, from one cause or another, have suffered much from neglect and absence of systematic repair, and in a few cases are absolutely ruinous. It is Mr. VERNON's opinion that the life of a building subject to the climatic influences of New South Wales is in many cases a comparatively short one, and unless frequent and periodical attention—particularly to outside repairs and protection from the ravages of the white ant—is systematically undertaken, a constant depreciation in the value of these buildings must ensue. Accordingly he suggests the advisability of greatly increasing the annual vote for "Repairs public buildings," even at the expense of projected new buildings, and the adoption of a system under which every building can be painted and repaired externally at least every fourth year.

THE suggestion of Sir SPENCER WELLS that a parish church should exemplify advanced principles of sanitation in order that they might be impressed on the minds of congregations, merits the attention of the clergy and churchwardens. There can be no doubt that attendance at services in many churches is more exhaustive to ordinary people than if they were engaged in manual labour during a similar number of hours. Why should stuffiness, like dimness of light, become associated with religious services? It may be said that the fault lies with architects and builders, but in the majority of cases they are not to blame. Clergymen have a fear of draughts, partly on their own account, partly for the sake of elderly ladies, and they imagine that ventilation is impossible without dangerous draughts, which is a delusion.

It is to be hoped the precedent set by the guardians of the Basford Union will not be generally followed unless it is intended to pay builders for their trouble in supplying the information. Casual wards are to be erected, and it is announced that "No tender will be received unless it is accompanied by a fully priced and monied-out copy of the quantities, containing every detail of expenditure upon which such tender is based, such quantities to remain the property of the guardians, and will be kept in the custody of the clerk." Payment on schedule rates has its advocates, but there must be a change in the system of tendering before it could be generally adopted. Hitherto, as all our readers know, the custom has been to expect a priced schedule from the successful contractor after his tender is accepted, and then only for the confidential use of the architect in squaring up accounts at the completion of the work. We cannot imagine that in this case the architect has approved of the innovation.

THE annual general meeting of the Liverpool Architectural Society was held on Monday. The annual report showed that the membership had increased from 115 to 125. The Council congratulated the Society on the result of the conference of architects recently held in Liverpool. It was hoped that before the beginning of another session they would have arranged with University College a system of education which would be beneficial to all young architects and students of architecture, and that the classes would be well attended. The following officers were elected:—President, Mr. H. HARTLEY; vice-presidents, Messrs. A. CULSHAW and H. W. KEEF; hon. librarian, Mr. J. L. BLAKEY; hon. treasurer, Mr. JAMES DOD. Mr. HARRISON, the retiring president, gave an address on climate and its effect on architecture. He said that the same climatic conditions which had so largely contributed to the original formation of races would always just as largely contribute to the modification of races by their wanderings, so as to make them stolid or reassuring, excitable or imaginative, passionate or phlegmatic, according to the amount of sunshine they enjoyed. The weather gave man his initial start as an architect, and it had continued and would continue to control his actions. Whether architecture was an art or profession, or whether the architect was born or made, he would always find himself to a very large extent subservient to climate.

HOUSE AT BROXBORNE.

THE house shown in the illustration was recently erected by Mr. J. A. HUNT, of Hoddesdon, from the designs of Messrs. NEWMAN & NEWMAN, F.R.I.B.A., of Tooley Street, London Bridge.

RESIDENCE AT MOSELEY, NEAR BIRMINGHAM.

THIS residence has recently been erected at the corner of Wake Green Road and Grove Avenue, Moseley, by Messrs. JAMES MOFFAT & SONS, contractors, from the designs and under the superintendence of Messrs. ESSEX, NICOL & GOODMAN, architects, of Birmingham and London. The buildings are faced with best pressed red bricks and Bath stone dressings, and are covered with brindled tiles.

THE NEW INN, GLOUCESTER.

THE ARCHITECTURAL ASSOCIATION.

THE eleventh ordinary meeting of the Architectural Association was held on Friday evening, Mr. H. O. Cresswell, President, in the chair.

Mr. H. W. Tomes was elected a member.

In connection with previous visits, votes of thanks were passed to Mr. E. W. Mountford, architect, and to Messrs. Holloway Bros., contractors; also to Mr. Aston Webb, Mr. J. Kelly and Rev. Father Vere, of St. Patrick's, Soho.

A visit for the following day, April 29, to the works of addition to the *Morning Post* offices, by permission of the President, was announced.

The lectures on painting, sculpture and allied arts, by Mr. C. Whall, Mr. Stirling Lee and Mr. Crace respectively, it was stated were open to any members who liked to attend them.

The soirée, it was announced, would take place on May 17. The House List, as proposed by the committee, was read, containing the names of Mr. E. W. Mountford as president, and of Mr. W. D. Caröe and Mr. Ernest Gale as vice-presidents.

Mr. P. GORDON SMITH then read the following paper on

Hygiene in its Application to the Arrangement of Buildings.

Mr. Gordon Smith said:—I have chosen the subject of hygiene in its application to the arrangement of buildings because it has fallen to my lot during the last twenty-five years to pay particular attention to, among other matters, the condition of the occupiers of a variety of different residential buildings in so far as that condition has been affected by the arrangement of the buildings in which they have resided. And I have had the opportunity of criticising the plans of many such buildings and of additions and alterations to already existing buildings, and I have also in many instances been able to observe the result, years afterwards, of arranging buildings in particular fashion. I have further had the benefit of association on nearly all occasions with medical colleagues who have assisted me with their special training and knowledge. Having had the advantage of such experience, it seemed to me when I was invited to give a lecture before the Architectural Association that I should best consult the wishes of the members if I endeavoured to lay before them some of the results of that experience.

It may be well at the outset that we should be reminded of some of the various ways in which a building may affect the health of those who have to occupy it, and in saying this I particularly wish to guard myself against being understood to imply that any of the defects to which I shall refer are themselves either the sole cause or the certain cause of the injury to health with which they are connected. It is probable that such evil results as do occur are brought about by a combination of conditions tending, during a longer or shorter period, to induce a state of health rendering the individual peculiarly susceptible to the particular disease that ultimately develops, and thus prepares the system to serve as a favourable soil for the progress of the disease. The arrangement of the building is one, and probably one of the most important factors in the causes of damage to health.

There appear to be three distinct sets of defects in a building which tend, in different ways and with different degrees of expedition, to bring about damage to health, and to foster, if they do not directly produce, conditions favourable to the development of certain specific diseases; thus what are most commonly spoken of and popularly understood as "sanitary defects" are probably the quickest to produce visible effect upon health, and are those which have been so aptly described as "filth diseases," and which convey, if they do not actually

cause, enteric fever, cholera, diarrhoea, and other disorders of the bowels produced mainly by excrement-poisoned air and water.

A second series of sanitary defects, entirely different and slower in their operation on the human subject than the last referred to, is that which tends to disorders of the bronchial type and to rheumatic complaints, to pneumonia, and in a great measure to phthisis and lung disease. This series is concerned with insufficient protection from extremes of temperature and from the effects of dampness and wet subsoil.

A third series of sanitary defects, and probably slower than either of the last, though undoubtedly not less certain in its effect, is the cause of a large amount of phthisis and other pulmonary diseases, of typhus fever and of ophthalmia, as well as affording a means of intensifying and spreading such zymotic diseases as smallpox, scarlet fever, &c., and likewise of encouraging depression and a tendency to mental complaints. These are more or less distinctly caused, or at any rate fostered, by insufficiency of air-space, overcrowding, excessive aggregation of persons in one enclosed atmosphere, deficiency of light and of sunshine.

It will be seen that the first of these three series of defects has to do mainly with drainage and water supply; the second relates chiefly to defective construction of walls, foundations and roofs; and the third to arrangement of buildings with regard to air supply and ventilation, light and distribution of occupiers.

It is this last-mentioned series of defects with which we are chiefly concerned on the present occasion. But I do not propose to occupy time by discussing the details of arrangement in regard to such matters as aspect and exposure to sunlight, air supply and ventilation.

That the influence which is exercised on the health of the inhabitants of a building by the particular arrangement of the building has, for upwards of thirty years, been recognised in regard to certain classes of building, will readily be admitted when we bear in mind that an ordinary hospital for a considerable number of patients is now always subdivided into separate blocks or pavilions, instead of being constructed in one single block of huge dimensions, as was formerly the case.

The sick, above all, need the best hygienic arrangements in order to insure and expedite their recovery, and wherever those arrangements do not exist, it is not difficult to detect the prejudicial effect upon the patients in the aggravation of their complaints, or the undue slowness of their recovery, and the tardiness of the healing of wounds, or possibly in graver indications or unwholesome conditions. We have all read, for example, of the difficulty of preserving the patients in a maternity hospital from the ravages of puerperal fever, and in surgical hospitals from the incursions of erysipelas.

Ever since the disastrous arrangements for the treatment of the sick and wounded troops in the Crimean campaign, 1853-55, the pavilion system of hospital construction has been accepted as possessing vast advantages over the older plan of arranging an unlimited number of patients in wards piled up several storeys in height, and often all round a quadrangle, as was the case in many old hospitals in all the countries of Europe. But even this pavilion system of construction, though undoubtedly right in principle, is now not infrequently terribly abused, as will presently be explained.

In hospitals for the reception of persons suffering from any of the infectious fevers, again, it is obvious that the hygienic arrangement of building has peculiar importance, since it is of the highest consequence that a patient admitted with any such infectious complaint must be so placed as not to risk contracting any other infectious disease during his stay in the hospital, and likewise so that a person sent there under erroneous diagnosis may be dealt with, with reasonable safety to himself as well as to other patients in the hospital. These special conditions obviously necessitate a special arrangement of building.

But it is not the sick alone who need peculiar hygienic arrangement in the building they occupy. Those who are reputed to be in proper health, both of body and mind, equally need care in regard to the arrangement of the building they occupy if their health is to be properly maintained, and wherever considerable numbers have to occupy the same building, as in an institution, the arrangement of building becomes a matter of vital importance.

Let us consider, for example, the subject of military barracks. The occupiers of these buildings are usually men in the prime of life, more or less in robust health, and selected after medical examination with due regard to their health conditions. And yet experience in the past has shown that unhealthy and badly-planned barracks have in time of peace killed or incapacitated the soldier to an extent almost equaling that of the most sanguinary wars. In our own army it was only after the Crimean War that public attention was directed to the subject. In 1857 it was found that, while the death-rate of the male civil population between the ages of twenty and forty years was 9·8 per 1,000, the mortality among the troops was

17'11, or nearly double. Subsequently an improved system of barrack construction was introduced which led to a considerable reduction in both the mortality rate, and the sickness of the troops; for whereas in 1857 the mortality among troops had been nearly double that of the male civil population of the same age, in 1876 the mortality among the troops had been reduced to nearly two per 1,000 less than that of the corresponding civil male population, and the hospital accommodation needed for troops has been diminished from 10 per cent. to 6 per cent.

In the French army, after the Franco-German war, similar improvements took place. M. Tollet writes that during the ten years ending 1882, France lost 40,000 men in the barracks, while some 60,000 men, who had entered the service in good health, were discharged on account of illness or infirmity. True, typhoid fever, consequent on bad drainage arrangements, was the cause of a large proportion (12,000) of the deaths, but that destructive lung disease, phthisis, appears to have been the main cause of this terrible loss. The success which has attended the improvement of barrack construction in our own country has been noted in certain other countries. In France particularly large improvements are being made. M. Tollet and M. Emil Trelat have paid high tribute to the work done in this direction in England, and both of them have urged on their own Government the extreme necessity for similar reforms in France. This is being gradually, though slowly, carried out, and M. Tollet has constructed several barracks arranged on improved principles under which the buildings comprise a number of one-storey detached blocks each to contain only a comparatively small number of men. In our own country the new barracks constructed under the Military Forces Localisation Act, 1872, comprise a number of wholly detached blocks, the residential blocks being restricted to two storeys, and holding some 80 to 120 men.

As with barracks, so with many other classes of building intended to hold a number of human beings. If we look at the modern prison we find the same subdivision into blocks or pavilions is now regarded as essential as in the case of an hospital. Wormwood Scrubbs Convict Prison is perhaps the best example of a recently-built prison in this country. It comprises four main pavilions and numerous smaller blocks, all detached one from another, affording accommodation, including hospital, for nearly 1,500 prisoners and a large staff of officers. A similar arrangement but with greater subdivision has been adopted in the new French prison at Nanterre, near Paris, which holds about 1,000 men and 500 women. These prisons afford a striking contrast as regards arrangement when compared with the prison of former days, such as Newgate and the Penitentiary at Millbank, or even the "model" prison at Pentonville in all of which aggregation of human beings in one block of buildings—in one enclosed atmosphere—was the common plan. In the still older prisons, which John Howard has so graphically described, it is certain that ignorance of the laws of health caused many of the prisoners to die, and a still larger number to be seriously crippled for life. Howard reports that "many of those who survive their long confinement are by it rendered incapable of working. Some of them by scorbutic distempers, others by their toes mortified or quite rotted from their feet, many instances of which I have seen." Howard made some valuable recommendations for obviating the defects of old prisons when a new prison was to be erected, one of these recommendations being far in advance of his time. He says, "That part of the building which is detached from the (surrounding) walls and contains the men-felons' ward may be . . . raised on arches that it may be more airy;" also "the infirmary or sick wards should be raised on arcades"—a plan which in recently-erected hospitals which I have seen both in France and Germany and to some extent in England, has been adopted for hygienic reasons.

In large modern workhouses it is customary to subdivide the buildings, even those for inmates in health, into separate blocks or pavilions, and to limit the number of paupers in each block to some moderate number, according to the class for whom it is intended.

And so, too, with regard to lunatic asylums, which are no longer arranged in one huge block of building, as at St. Luke's and at Bethlehem Hospitals, at Hanwell and Colney Hatch, but are invariably constructed in a series of more or less distinct blocks or pavilions, each to hold a certain moderate number of patients, and so that the sun in clear weather may shine between the blocks, and at some time during the twenty-four hours into all the rooms. For it has to be remembered that light and cheerfulness, which are so necessary for all, are specially useful in the treatment of all mental diseases.

Nor must it be supposed that the arrangement of building is of importance solely to buildings of the institution type. It will suffice here for me to point out that persons who reside in cottages arranged on the principle of what is known as back-to-back houses are peculiarly subject to prejudicial effect of the hygienic defects inherent to that system of house-construction. This is very clearly shown by the following table, which has been adapted from a report upon back-to-back house construc-

tion, which Dr. F. W. Barry and I prepared for the Local Government Board in 1888:—

No. of Registration Districts.	Population (1881)	Percentage of Back-to-back Houses.	Mean Annual Death-rate per 1,000 of the Population for Five Years, 1879-1883.				
			All Causes.	Principal Infectious Diseases.	Phthisis.	Other Pulmonary Diseases.	Diarrhea.
9	8,713	0	27.5	4.5	2.8	6.6	1.42
13	11,749	23	29.2	4.8	3.3	7.8	1.55
12	11,405	56	30.5	6.5	3.6	7.9	2.12
1	892	100	38.4	8.7	5.2	9.2	3.36

The districts referred to are certain of the 1881 census-enumeration districts, and it will be seen that as the percentage of back-to-back houses to total houses increases, so is there increase in the mortality rate from phthisis, in that from all causes, and likewise from certain other specified diseases. The importance of these rates is all the greater because, with the exception of the means of through ventilation, the back-to-back houses in the district in question were, as a whole, in a better sanitary state than the through houses.

I have thus far endeavoured to show that the health of the dwellers in sundry kinds of buildings depends to a great extent upon the arrangement of the building in which they live, or at any rate that the arrangement of building may influence their health conditions. In the case of general hospitals, as I have said, this is very generally recognised, since the conditions under which a patient may be maintained during his stay in hospital may either expedite or retard his cure and discharge. But if it be admitted that certain good hygienic arrangements of building are really useful for the sick, it can scarcely be denied that those same arrangements are at least desirable for those who are reputed to be in health, and might be useful as auxiliary means of maintaining a certain degree of healthiness. The value of the hospital arrangement of building or of some modification of it in the case of barracks, prisons, asylums and workhouses as an agent for the prevention of disease is, as I have shown, now very generally recognised; but I notice that very many residential institutions, intended to receive large numbers of persons reputed to be in health, are still frequently erected on an obsolete and defective plan. This is specially the case with charitable institutions of all kinds, and particularly so with institutions for the reception of children.

Nearly all institutions which depend for their very existence upon voluntary support are, more or less, crippled for want of funds, and their usefulness often leads those who have the management in their control to endeavour to do more than the available funds will permit to be done properly. Thus we find schemes are frequently promulgated for extending or rebuilding all sorts of institutions, such as orphanages, asylums for idiots, the blind, the deaf and dumb, waifs and strays, and all kinds of schools, in regard to which the chief aim of the promoters is to so enclose a building as to afford shelter to the largest possible number of individuals which the available money will permit.

Now for the class of institution to which I refer. There is, so far as I am aware, no code of rules for the guidance, in a hygienic sense, of those concerned. Hospitals have been written about almost *ad nauseam*; barracks are designed and built more or less directly under Government control. Lunatic asylums to a great extent follow hospitals, and come in for the criticism of a responsible department of Government. So too, do workhouse buildings of all kinds, and prisons are dealt with directly by Government. Public elementary schools again come in for official criticism, but residential schools (with the exception of those for pauper children) and charitable institutions of the kind generally are subject to practically no superior control whatever in regard to the arrangement of building. Nor is there much literature upon the subject. Schools, so far as education is concerned—that is to say, so far as regards the schoolrooms, class-rooms and conveniences—have been written about by the architect to that department, and an official paper bearing on the subject is issued by the department. The Association of Medical Officers of Schools have dealt with certain questions of school hygiene as concerning their own responsibilities; but, viewed as a whole, there is very little to assist either the architect or his client in all that concerns the arrangement of these institutions, and especially the residential institution of the class.

As a result of this absence of any definite principle in the arrangement of such buildings, we find all sorts of plans are adopted, some good, some indifferent, and some bad—very bad.

We accordingly find colleges and institutions intended as residential places for numbers of young persons reputed to be in good bodily health, though in some instances they may be

blind, or deaf and dumb, or of weak intellect, or more or less destitute or deprived of parental care, as orphans, arranged upon all sorts of plans, the residential rooms being arranged sometimes even over the domestic offices, round the four sides of a quadrangle, or in buildings several storeys high in the form on plan of the letter E or the letter H, and of a size intended to hold hundreds of persons.

The institutions to which I refer, being commonly intended for young persons, have, I think, taught lessons which the architect, among others, would do well to study. Poor-law institutions for children have needed, and have received, a very large amount of attention, and have been observed by many experts. The child may be regarded as a sensitive instrument which indicates very promptly and with much precision every variation of the health-conditions in which he is placed, and the experience of the large Poor Law schools is most instructive.

Some thirty or thirty-five years ago the objections to keeping the children in the workhouses, especially in the Metropolis, came to be recognised, and moreover the space they occupied began to be wanted for adults, and accordingly they were in many cases removed to separate school buildings, residential of course, on large open sites outside the towns, and arranged on what was considered the best plan. Notwithstanding, however, all the advantages under which these new institutions were placed, the result, after long and often very careful trial, was far from encouraging. Ophthalmia, diseases of the skin and scalp, and other troublesome disorders prevailed in these schools to an extraordinary extent, and in some instances seemed irremedial. Specialists were called in, enormous expense was incurred in medical advice and treatment, but with only partial or temporarily successful results. As regards ophthalmia, Mr. Nettleship, the eminent oculist, who was consulted in regard to all the metropolitan pauper schools, numbering many thousand children, has asserted that this disease "is the touchstone of the general healthiness of an institution," and he further remarks that "where many persons are herded together, their eyelids show sooner and more certainly than any other part if the conditions of vigorous health are not complied with." Dr. Mouat, again, who had wide experience in this class of institution, says "the stunted, impaired general health and feeble bodily powers of too many of these children are not removed or corrected by massing them together in large buildings or groups," and he points out that "there is a large and possibly increasing factor of imbecility, idiocy and nervous disorder generally, and some of the more immediate results of scrofula at the critical periods of life, which may be due to the insanitary conditions" inherent to the aggregation of large numbers of children in huge buildings.

It is this aggregation of human beings in vast buildings to which I wish to direct special attention. The evil results, due in a great measure to it, have been particularly noticed in Poor Law institutions, but those same evil results are not by any means unknown in other institutions. Ophthalmia has been found in them, though perhaps in a less aggravated form, and tendency to other disease is commonly experienced in them, but its severity is less, by reason probably of a variety of circumstances, such as the superior condition under which the children in those other institutions are reared before being sent to school, the periodical change the children enjoy in the three usual annual vacations, and so forth. These large institutions, with vast aggregations of children under the one roof and in the one atmosphere, have come to be regarded as a failure on hygienic grounds, and as with hospitals, subdivision of building with comparatively small groups of human beings is recognised as one of the chief means of maintaining a proper standard of health among the occupiers of the institution. So important is this arrangement of building regarded that it was determined a few years ago to cut up the huge main block of the Central London Schools at Hanwell. That building, originally designed to be partly three and partly four storeys high, with a length of frontage of some 650 feet, was, under the superintendence of Messrs. Henry Jarvis & Sons, the architects, subdivided into five distinct blocks. Gaps 16 feet wide and open from the ground upwards, were cut through the building in four places, so that the number of children accommodated in it was not only reduced, but the children were completely subdivided into comparatively small groups, and the whole arrangement became more assimilated in principle to that now commonly adopted in the construction of large hospitals.

This principle of subdivision of the children into small groups is by no means new. In Switzerland the family system of schools was introduced by Pestalozzi as long ago as about 1760; and the reformatory school at Mettray, in Belgium, on a similar system, has been in operation for about fifty years. In England there are several examples of the system which have been in existence for a long period, and the condition of the children in them has been carefully observed and noted. Some fifteen years ago the suitability of the home or cottage system of training and educating the children of the poor was the subject of an investigation by my then colleagues, Dr. Mouat

and Captain Bowly, R.E., and their report, which was subsequently published, shows that, while the system was generally adopted with the primary object of securing greater individual attention to the children for purposes of moral training and education, the hygienic advantages were very considerable indeed. And since the date of that report, as indeed before it in several instances (chiefly in South Wales), a considerable number of Poor Law schools on the cottage-home system have been built, and the result, so far as health is concerned, has been highly satisfactory. There are, as may be expected, many varieties of what is known as the cottage-home arrangement of school. Some would be more correctly described as on the separate block system, since the number of children in each "home" is large, there being in one or two instances as many as fifty children in each house, and in one, the Philanthropic Society's Farm School, near Redhill, even sixty, but the cottages at that institution are scattered over a very large estate of some 300 acres, and the school is a reformatory for boys who are all of an age greater than that of the children in ordinary schools and orphanages. The houses of the London Orphan Asylum at Watford hold fifty children each, as do also the "homes" in a few of the larger Poor Law schools on this system. The houses of the Little Boys' Homes at Farningham hold thirty children each, and so do those of the Birmingham Poor Law Cottage Homes, and some others. The Leicester Guardians adopted the excellent plan of building cottages for their pauper children on different scales, some holding sixteen children, some twenty, and some twenty-four children. In South Wales there are several Poor Law schools on this system, where the imitation of the natural family is approached more closely, the number of children in each cottage being only ten or twelve—a plan which obtains also in some excellent charitable institutions of the kind, such as Dr. Barnardo's Village Homes at Ilford, and the Princess Mary's Cottage Homes for Girls at Addlestone and others. This system of *segregation*, as distinguished from the common one of *aggregation*, is of the utmost hygienic importance where children are concerned. At some cottage-home schools a marked improvement in the health of the children has been noticed on their removal to them; thus, in Dr. Barnardo's thirty cottages it is reported in 1878:—"A great improvement in the general health and appearance of the children has taken place during the last twelve months, and this is attributed by the governor entirely to their removal from the building where they were formerly all housed together to the new cottages." And I am inclined to attach importance to it, not only in the domicile of the children as a whole, but in the individual rooms where they are assembled—in the dormitories, in their day and play-rooms, and especially in their school and class-rooms. The question of the number of children who may properly be assembled together for several hours in a schoolroom seems to have never been considered in its hygienic aspect, the main point recommended for attention in planning a schoolroom being (to quote from an official document) "to seat the children in the best manner for being taught." Mr. Nettleship, in noticing this tendency to aggregation of unlimited numbers of children in a large school where there was prevalence of ophthalmia, observes that hardly any attempt had been made to treat the children otherwise than collectively. In the official document already referred to it is pointed out generally that the observance of sanitary laws is as important in a school as in a hospital; hence it would seem reasonable to assume that children cannot be aggregated in a schoolroom with impunity any more than sick persons can safely be aggregated in a hospital ward. The comparatively short space of time at a stretch that children are kept in a schoolroom may cause the prejudicial effects to be less readily observed than in the case of patients continuously occupying a sick ward for several weeks; but that evil results ensue from massing large numbers together in schoolrooms must, I think, be admitted, and those evil results will be demonstrated with more or less rapidity, and will be intensified or diminished according to a variety of circumstances, such as the general health-condition of the children, the amount of floor-space and cubic-space allotted to each child, and the efficiency of the ventilation and the warming of the room.

In view of these considerations I look with no small anxiety at the enormous aggregation of children in many of our public elementary schools where they assemble, not only in large numbers in their several school and class-rooms, but where those rooms are piled up in several storeys and arranged so that in many instances the vitiated air is equally diffused throughout the entire building by means of the staircases and corridors. I cannot but think that in time to come these huge school buildings will be the subject of condemnation on account of their arrangement being found to be defective on hygienic grounds. Already the large increase of diphtheria that has taken place in England since elementary education became compulsory in 1870 is attributed in some measure to the association of children in vast numbers in the public elementary schools, and over and over again it has been ascertained that

the village school or the Board school has played the chief part in fostering and encouraging local epidemics.*

Hence if the aggregation of children is a source of evil in those day schools where the children assemble for a few hours only at a time, how much greater is likely to be the evil from similar aggregation where the children pass the whole twenty-four hours of every day in schools and orphanages of the residential type?

I referred at the commencement of my lecture to the way in which the pavilion system of hospital construction is occasionally abused. That system was introduced mainly, no doubt, to secure improved ventilation in the wards; but it also possessed the advantage of allowing the subdivision of the patients and of the more effectual classification of them, the surgical from the medical, and of grouping them with greater comfort to themselves and with greater efficiency, convenience and economy of nursing and administration. That the subdivision of the patients in a large hospital is of value as an important factor in the health-conditions of the institution will be admitted by every one who carefully studies the statistics and the mortality rates of hospitals. The late Dr. William Farr, of the statistical branch of the Registrar-General's department, says:—"The collection of a number of persons exceeding those of an ordinary family, under one roof, has hitherto had a tendency to increase the dangers of disease; for several diseases are, like fire and ferments, diffusible. The danger is increased when all the patients are sick, for their breath and excretions spread through the wards. The dangers, too, are likely to increase in a faster ratio than the numbers."† I wish to lay special stress upon this assertion of Dr. Farr's that the dangers of aggregation are "likely to increase in a faster ratio than the numbers of patients." As bearing on the same feature, I may remind you of what is said by Mr. Lawson Tait, the eminent surgeon, where, in his work on "Hospital Mortality," he contends that his statistics prove "that after the number of beds in a hospital exceeds 100, the risk to life becomes so much increased that it is questionable whether any hospital should be of larger size than this. If circumstances make it necessary that the hospital should be larger, most undoubtedly special arrangements and precautions should be taken to obviate the extra risk which is involved."

In view of these grave assertions of men whose experience and position entitles their opinions to much weight, it is indispensable to arrange a pavilion hospital in such a manner that the several pavilions shall be absolutely detached one from another, and so that the wards in every block should not intercommunicate with each other so as practically to have one atmosphere common to all of them, a point of importance, be it remembered, in a cottage hospital (where surgical and medical cases are received for treatment) as well as in other hospitals. This arrangement of complete separation of the several blocks or pavilions of a hospital is well understood by our friends in France, Germany and some other countries, where the pavilions in certain modern hospitals are placed at a distance apart without any other means of communication with each other and with the administrative offices than an open path or roadway; and moreover, the blocks are often only one storey high, and consequently contain only a very restricted number of patients. Now, if we look at the arrangements of our hospitals at home, we find a condition very different from what our foreign friends consider desirable. Which hospital shall we choose for examination? St. Thomas's Hospital is one of our most modern, erected at great cost, in a position where it claims the attention of foreigners, and competes in magnificence with the Palace of Legislature opposite to it. At this hospital we find huge wards piled up one upon another in four storeys, with a basement for stores, &c., beneath them, and dormitories for nurses and servants in an attic above them. Not only are these wards intimately connected with each other by spacious staircases from basement to attic, lifts for patients, lifts for coals, food, &c., and shoots for ashes and soiled linen, but as if there had

been a distinct intention to assimilate the air throughout the interior of the whole institution as much as possible and to counteract the effect of the "pavilion" system, the several pavilions, each holding some 112 patients, are connected together by enclosed corridors in the basement storey, in the ground storey and in the one-pair storey. So, too, at some of our best Poor Law infirmaries, the pavilions are joined together end to end instead of merely being kept separate and merely connected with the staircase by means of a short corridor. These arrangements are directly the reverse of what is aimed at in the best examples of modern hospital construction in France and Germany. At the great Friederichsheim Hospital at Berlin and at the Moabit Hospital, also at Berlin, at the Eppendorf Hospital at Hamburg, at the St. Denis Hospital near Paris, and others, the ward-blocks are absolutely detached, and at some, as the University Hospital at Heidelberg, the ward blocks are connected by a mere covered way open at the sides. No difficulty whatever is experienced in the administration of these hospitals, consequent upon the distance to be travelled in the open air from the nurses' quarters and kitchen offices to the several ward-blocks, and the hygienic advantage of complete separation of the patients into small groups is appreciated by the medical staff of those hospitals. This segregation of patients is carried to much greater length in the best modern foreign hospitals than in England, for, as a general rule, the ward-blocks rarely exceed one storey in height, and practically are never more than two storeys high, while the number of patients under one roof, or in one ward is much less than is the case in our English and Scotch hospitals. So, too, are the buildings spread over the site, so as to give a far larger area of site per bed than is customary in our own modern hospitals. At the great University Hospital at Halle, in Germany, the arrangement resembles a collection of small hospitals rather than one huge hospital like our own St. Thomas's Hospital.

Another hygienic arrangement common in continental hospitals is the plan of forming verandahs, balconies and even detached outbuildings or summer-houses, in which a large proportion of the patients are placed, while still in bed, practically in the open air, by night as well as by day, during some four or five summer months of the year, and I am assured by eminent surgeons and medical men that this arrangement is attended with great benefit to the patients. The plan is growing in England, and has been found in several instances in my own knowledge to be most beneficial. This plan of moving the patients out of the general wards during the summer affords the opportunity for allowing those wards of the hospital to be emptied for purposes of cleansing and sweetening; indeed, an eminent German physician once told me in Berlin of the hygienic value attaching to the arrangements of a hospital admitting of every ward being allowed to "lie fallow" for a period every year during which the window-sashes are removed and the interior exposed to wind and weather. This is in accordance with the experience of a fever hospital with which I am associated, where it has been found and recorded that after every time of purifying, whitening and painting the wards, the patients with scarlatina first received into them do better than those received into wards which have not been recently purified.

It is unnecessary for me to deal generally with the question of arrangement of domestic buildings in their hygienic aspect, since the need for ample means of light, access of sunshine and circulation of air about them must be well known to all. But there are one or two points about this class of building to which I must briefly refer. There are plenty of examples of blocks of so-called "model" dwellings in all our large towns which may be pointed to as "models" of what to avoid. In London we may easily find instances of blocks six and seven storeys high directly connected at right-angles, and even at acute angles, so that the sun (even when it does shine) can never reach many of the windows, and so that there is inevitable stagnation of air; or, again, that are arranged (as in the diagram) in streets—*culs de sac*—only 28 feet wide. These errors are common enough, owing to the absence of any sufficient controlling power, and though they are fully recognised by the architect and by the County Council too, they are nevertheless often committed under professional superintendence in order to comply with the client's demands for adequate if not excessive return for outlay.

In many of the earlier-built blocks of artisans' dwellings it was common enough to arrange them in such a manner that many families were aggregated together in the one enclosed atmosphere of a building many storeys high. These buildings were very disappointing in their wholesomeness, and the evidence given before the Royal Commission on the Housing of the Working-Classes, 1884, affords some suggestive information bearing upon this important question of hygiene in its application to the arrangement of buildings, while the density of population, in some instances reaching a rate of about 1,000 to the acre, was shown to be very high. The mortality rate in these huge blocks of artisans' dwellings is commonly higher than it ought to be, when it is borne in mind that the

* Dr. Thorne, in his "Progress of Preventive Medicine" (pp. 42 and 43) records that in an investigation he made into an outbreak of diphtheria in Essex, "the incidence of the disease upon children from three to twelve years old was about 50 per cent. greater upon those known to have attended school than upon the remainder." He also quotes from Mr. Power's report on an outbreak at Pirbright, "on four successive occasions while the village school was open well-marked diphtheria occurred among the scholars . . . and this although the school premises were free from recognisable sanitary defects, and although the school was not, after its first closure, reopened until the disease had seemed extinct in the parish and careful measures of disinfection had been used." Dr. Thorne further points out that the reopening of the school appeared on each of the four occasions to be responsible for giving a serious quality to the resulting diphtheria, and he adds that there are grounds for believing that the aggregation together of cases of diphtheria and of allied throat affections under circumstances such as those obtaining in elementary schools, constitutes one of the conditions under which a form of disease of particular potency for spread and for death may be, so to speak, manufactured.

† "Vital Statistics," p. 423.

tenants are to a large extent specially selected for their respectability and other good qualities. I do not imply that any system of selection is intentionally adopted by the landlord, but that in effect the tenants come to be sifted down, so to speak, to a picked set of respectable families, the average being more steady, sober and reputable than the average of the same class living elsewhere. Notwithstanding this advantage, the difference between the mortality rate in these block dwellings and in the whole Metropolis is often very small, and this, too, even in the rate of infant mortality. Thus, it has been stated that in a population of between 6,000 and 7,000 occupying upwards of a dozen different estates of block dwellings, the general death-rate was 15·6 per 1,000, while in the whole Metropolis it was 18·5 per 1,000; but in those same dwellings the rate of infant mortality was 140 per 1,000 births, or only six less than in the whole Metropolis, where the rate during the same period was 146 per 1,000 births, a difference in that most important matter which is so small as to leave much material for reflection and inquiry.

Closely akin to the subject of block-dwellings is that of common lodging-houses and so-called "refuges" for homeless persons. When it is borne in mind how the persons resorting nightly to these dwellings carry disease about and spread it all over the country, it will be admitted that improvement is desirable in the arrangement and other conditions of the buildings they inhabit. It has been noticed over and over again that where extensive works, such as railway construction, water conduit works, canal works, and the like, are in progress, and a large number of navvies have to be temporarily housed, various kinds of disease commonly break out among them, and are often spread from them over very wide areas. Now, if we look at the conditions under which these people are usually housed, we shall find them crowded together night after night in large numbers with the scantiest amount possible of space, cubic and superficial. The contractor's navvy is housed in a wooden hut, the lodger in the common lodging-house is crowded into an indifferently ventilated dwelling, and the houseless poor seek the shelter afforded either by the charitable or the parochial authorities in such refuges as are available, and there are many, but the hygienic arrangements of them generally leave much to be desired. They often hold some hundreds of lodgers, the dormitories having as many as fifty to seventy or more beds in them, and this in two or more storeys. These conditions are obviously not calculated to promote the health of the lodgers, but rather to foster and encourage any latent disease that may exist among them.

In my opinion it is most desirable that the building should be so arranged as to allow the large numbers received into such lodging-houses and refuges to be subdivided into small groups, the dormitories being severed as much as possible, aerially, one from another, and the number of lodgers in each reduced to a maximum of some twenty, unless the customary amount of superficial and cubic space to each lodger be largely increased.

It will be gathered from what I have said that great hygienic importance attaches, in my humble opinion, to such arrangement of building as will insure the segregation of human beings as far as practicable where they have to be collected together for special purposes, and it is because I have been led to this opinion by many years of observation that I venture to urge it as strongly as I do. I have noticed that, even quite recently, competition plans have been, or are to be, invited for large schools—in one case a day-school for some 1,200 children, and in another a residential school for some 700 boys, with an intimation that accommodation will be needed later on for about 500 girls—and so far as I have been able to gather the really important questions of the hygienic arrangement of buildings and of the disposition or grouping of the children for purposes of health are practically ignored, or are left to be determined on the lines that it has been the custom to follow for very many years, and which I venture to think ought to be regarded as obsolete.

I do not doubt that much may be said in favour of the present system of arrangement—the aggregation system I will call it—on the score of economy, but I am inclined to demur to a good deal that has been urged on this head. Time, however, does not allow of my going into the question of relative cost of the two systems on the present occasion. But I will conclude with the hope that the points I have urged may be helpful to the architect in the advice he may be called upon to give his client as to the best way, from a health point of view, of arranging the building he is commissioned to design.

Mr. H. D. SEARLES WOOD proposed a vote of thanks to Mr. Gordon Smith for his paper. The paper would be valuable, he thought, because it would strengthen the hands of architects in dealing with their clients by demonstrating the proper hygienic conditions to be secured; clients often have compelled their architects to do what was contrary to true hygienic principles. A common error of the public was to confound hygiene principles with sanitary matters only. There was need of

reform in factories, the state of which, as a rule, was unsatisfactory.

Mr. SAXON SNELL, jun., seconded the vote. Segregation instead of aggregation, all he thought would prefer, but unfortunately architects could not always have their own way. Miss Nightingale's advice to designers of hospitals was to take care that their buildings should not do harm to patients. Mr. Snell then alluded to the old story of persons counteracting the working of ventilating appliances and inlets for air by neglecting to keep them in order, stopping them up, &c., rendering useless all precautions taken by architects. In some cases, buildings in which hygienic principles had not been attended to proved satisfactory owing to cleanliness being a main point attended to by those in charge of them.

Mr. BERNARD DICKSEE said he was in favour of internal corridors for hospitals rather than having to go out in the open air.

Mr. BRODIE thought it was time people should know that hygiene was not confined to sanitary matters.

The PRESIDENT said Mr. Smith had alluded to the want of literature on this subject, and he considered no one was better qualified to supply this want than Mr. Smith. He then put the vote, which was carried by acclamation.

Mr. SMITH, in replying, said he had contributed articles to a magazine, the pith of which he had endeavoured to lay before them that evening. Mechanical ventilating arrangements were, he said, generally utter failures—at any rate, they should be used with great caution. The bridges at the Hanwell establishment, he explained, were emergency exits in case of fire, and not intended for administrative uses. Covered ways were not essential for conveying food from the kitchen to the buildings. It was an everyday experience in many institutions that joints, &c., could be served out hot without difficulty. Quadrangles, he said, might be objected to, but it should be remembered that where they existed, as at Oxford and Cambridge University colleges, the buildings were unoccupied for some months during the year, which made a great difference.

HISTORY AND DEVELOPMENT OF PATTERN DESIGNING IN TEXTILES.*

(Concluded from page 280.)

IN the same manner as in Spain, the Arabs exercised their industrial and artistic skill in the sea-girt Etnean island of Sicily. This grand era of textile industry did not commence until after the conquest of Sicily by the Normans. It bears the name at the present day of the "Saracenic-Sicilian" epoch of textile art, and a large number of splendid examples of this period are preserved in our churches and museums.

The Normans, in quest of booty and territory, took possession of Sicily in the eleventh century. After settling there, their kings conceived the idea of augmenting their power by developing the resources of the country. This idea was fully carried out by the best of the Norman kings, Roger II. (1101–84). He knew how to encourage the rearing of silkworms and the manufacture of silk, which was carried on in Sicily by Saracenic weavers. Of great importance to the development of silk manufacture in this country was King Roger's campaign to Albania, the present Greece. He led away captive all the men and women from Corinth, Thebes and Athens he could find who knew how to weave silks, and carried them to Palermo. He built dwellings for them, and compelled them to weave for him and to improve the silk industry. In order to insure the prosperity of the latter it was declared to be a royal monopoly. Mulberry trees were cultivated in all parts of Sicily, and silkworms were imported and reared with great perseverance to obtain raw silk.

An interesting royal silk factory was established at Palermo. This factory (the so-called Hotel de Tiraz) was in the royal palace, and owed its foundation to the Kelbij Amirs, who ruled Sicily, as vassals of the Fatimas, in the ninth and tenth centuries.

A writer of the twelfth century, Hugo Falcandus, draws the following picture of it in his description of Palermo:—

"It is impossible to pass over with silence the celebrated workshop adjoining the palace, in which silk is spun into different coloured threads, and these threads combined to form fabrics of several varieties. Here one can see stuffs made of single, double and threefold thread, which are less expensive, and require less skill than those made of sixfold thread, more raw silk being used for the more substantial materials. Fabrics are ornamented with a circular design, requiring for this reason great skill and a high price. There are also numerous ornamental patterns of various kinds and colours

* A paper by Herr Paul Schulze, Conservator of the Royal Textile Collection, and Lecturer on Art in the Royal Weaving School at Crefeld, read at a meeting of the Society of Arts and published in the *Journal*.

woven in gold and silk threads. To this class of goods the beautiful effect of the design is often illuminated by the brilliant flashing of precious stones."

Under King Roger's supervision, the Hotel de Tiraz maintained its special character and excellence of work. A silk manufacture sprang up from it, which not only answered King Roger's expectations with respect to the increased prosperity of his country, but also had its influence upon the whole of Italy, as the industry got a footing there also, and laid the foundation of the opulence and power which were to accrue to the towns of Central and Northern Italy. A great quantity of splendid types of Siculo-Arab work, in the twelfth century, enables us to form some conception of what manner of stuffs William of Palermo wished to speak of when he described the palace of Roger of Sicily:—

De drap de soie à or ou vres
A œuvres d'or et à peintures,
A maintes diverses figures
D'oïsiæ, de bestes, et de gens.
Les chambres furent par dedans
Peintes et bien enluminées.

Let us now examine the designs upon these fabrics made at Palermo by the Saracenic and Greek weavers. We find that they used the same patterns as in their native countries—symbolical animals, enclosed in large or small circles, in contact with one another or by polygons, just as in the Byzantine work.

In the Royal Textile Collection at Crefeld there is preserved a little fragment of the stola in which the bones of King Roger II. are enveloped in his tomb in Cephalo, near Palermo. It is quite possible that this splendid purple coloured fabric was manufactured at Byzantium and brought home by King Roger after his campaign against Emanuel of Constantinople (1147). Other samples of this period bear more distinctly the character of Saracenic fabrics. The designs upon them are composed of stripes in different colours, red, green, blue and white, with ornaments of gold threads. In the stripes we often see Arabian inscriptions. A rare fabric, which came from the church of St. Mary, at Danzig, shows an Arabian inscription, "assultan al alim," which means the wise Sultan.

At Ratisbon are two surplices which the German Emperor Henry VI. presented to the Ratisbon Cathedral. He inherited Sicily by his wife Constance, the heiress of the Norman crown. With this Emperor the vestments of the Norman kings, manufactured in the Hotel de Tiraz, and bearing Latin and Arabian inscriptions, passed into the possession of the German Imperial family, and until 1797 were the official robes of the emperors of the Holy Roman Empire of the German nation. The designs upon the two Ratisbon surplices are also striped in the same way as those already described. The Arabian inscriptions on these fabrics are very important. One of them means "Glory, victory, and long life." The other proves without doubt the origin and age of these materials. It runs:—"This holiday garment was made by Master Abdul Aziz, in his factory, for William II." This was a Norman king, reigning from 1166-89. Apart from royal robes, the most handsome stuffs were devoted to the manufacture of the dresses of honour which Mohammedan princes were pleased to bestow on those who had succeeded in winning their royal approbation. A welcome ambassador, the bringer of good news, a court favourite, a servant who had done something (or nothing) that pleased his master, would be so rewarded, the robe being appropriate to the rank of the person to be thus distinguished. To give the wrong dress would be like bestowing the Order of Saint Michael and Saint George on an Indian officer, or the C.I.E. on an Australian—as is said by Mr. Stanley Lane Poole in his clever book about the art of the Saracens in Egypt.

The ornamental use of letters is a characteristic of Islam art. Mohammed, in his intense eagerness to suppress the worship and making of idols, has repeatedly pronounced in the Koran a strict prohibition against making any images of created beings. He considered such acts to be an encroachment upon God's omnipotence. According to the words of the prophet, the creations of unbelievers in this world will mount upon their backs in the day of judgment, with horrible forms and distorted faces, and the unbelievers will be forced to bear this horrible burden for ever.

To compensate for the loss of figured patterns, the skilful Mussulman took a very sensible course in conveying, with the assistance of his letters, so well capable of this treatment, the ideas expressed in other styles by allegories and symbols. Thus we find the walls of mosques and palaces richly decorated with sentences from the Koran and holy books. Their woven goods also show the employment of letters in their designs. However, the subtle expounders of the Koran soon found a means of evading the strict letter of the law, and admitted a more lenient interpretation of it. After this only, naturalistic imitations of living creatures were considered unlawful, whilst a conventional treatment, which nearly represented the genus of the creature, as well as fantastic forms, which owed their

origin to the inventive minds of the Orientals, were permitted. The employment of Christians to weave such unorthodox designs as beasts and even human beings, however, was in itself a salve to the Moslem conscience; for the Christian weaver, and not the Mohammedan wearer, might be expected to receive the punishment. Similarly the prohibition against the weaving of silk dresses, which Mohammed considered should only be worn in heaven, was held not to extend to the use of silk fabrics with a linen warp; and the prohibition against the drinking of wine is to-day not referred to the drinking of champagne, because Mohammed, who did not yet know this noble drink, was unable to forbid it.

In the textile fabrics made by the Moors in Spain we can see abundant evidence of their strict avoidance of figure subjects. The Arabs, with their peculiar capacity for mathematics, preferred geometrical designs, and such composed only by ornaments and conventional flowers. These designs might be the precursors of the splendid pomegranate compositions on the velvet, silk and brocade stuffs which were manufactured in the fifteenth century in Northern Italy. We learn from various writers how important Moorish manufacture in Spain was from the tenth to the fifteenth century. The towns of Almeria, Granada, Cordova and Seville were particularly famous for their productions. In Seville 60,000 looms were said to have been active, whilst in another district nearly 3,000 localities were engaged in the art of weaving.

The combined work of the Greek weavers transported to Palermo by Roger and the Saracens introduced a new style of textile designs, which by the skilful combination of graceful line and floral ornament with figure-drawing, appreciated from the earliest times by Oriental taste, form the most interesting and attractive textile products of all ages. Elegantly-drawn tendrils form the groundwork, on which move slender and lithe-limbed animals. The Mussulmans coming over from Africa brought along with them a knowledge of the fauna of that vast continent: its giraffes, its antelopes, its gazelles, its lions and elephants; they knew the parrot of India and the hunting lion—the cheetahs—that were found in Asia, and when the stuff had to be wrought for European wear, imaged both beast and bird upon the web, at the same time that they wove a word of greeting in Arabic, to be read among the flowers. The Grecian newcomers brought fresh designs, which were adopted sometimes wholly, at others but in part, and mixed up with the Saracenic style. Human figures are plentifully interspersed; men, and more often maidens, hunting animals, are enclosed in characteristic surroundings, such as castles, shells and nets, like the bewitched princess in the contemporary fairy tales of the "Arabian Nights."

It is interesting to learn that these designs often have a symbolical meaning. For instance, a lion seizing a duck pursued by an eagle means that the possessor of this garment was valiant enough to snatch the booty from the claws of the eagle, the eagle signifying luck and riches; the lion, power and government.

From a pattern upon a piece of silk of the thirteenth century, showing a lion and hoopoe, it may be inferred that the fabric belonged to the robe of a strong and wise sovereign, since the hoopoe signifies wisdom. Moreover, a little inscription in the narrow border of the stuff says, "The Wise."

Another design shows a woman catching a hare with a net and holding by a chain or cord a hound and a spotted cheetah. Beneath this we see a woman with an eagle. From Arabian symbolism we learn from Professor Karabacek, in Vienna, that the catching of the hare signifies opulence, marriage and increase of family. To dream of riding on an eagle's back foretells riches, and if a person should see a woman carried on an eagle's back, he will eventually arrive at government.

Another design of that period, often used in Catholic churches, is the following:—Two stags, fastened with chains and turning their heads to heaven, kneel on a flowery ground, surrounded by large connected hexagons. Dewdrops and sunbeams fall from the disc of the sun, which is partially hidden by clouds, where two eagles are sitting. In this pattern the stag is supposed to be the symbol of the human soul, weary of life and yearning for delivery from its mortal body. We shall not be mistaken if we find in this interesting design a reference to the beautiful words of the forty-second Psalm, "As the hart panteth after the waterbrooks, so panteth my soul after thee, O God."

In another stuff a lion steps from the winged disc of the sun, holding in its claws a little animal. Another design shows a fountain, the structure being decorated with dragon heads from which hang scoops. Two girls carrying hares stand at the side of the fountain. Hounds and cheetahs lap the water flowing from the basin. Lastly may be mentioned an interesting design, woven in gold threads, in which we see alternate repetition of stars and a twisted ribbon bearing an Arabian inscription, above which a pigeon is flying underneath a large crown. We are thus able to discover a great number of interesting particulars in these fabrics.

But let us pursue the advancement of weaving in Europe.

Whilst at the Hotel de Tiraz at Palermo these splendid silk fabrics with gold thread designs, those magnificent velvets and those embroideries, bearing precious stones in gold settings, were being manufactured, we see at the end of the thirteenth century the towns of Italy enter into competition with Palermo, and thus especially as regards those towns in the north of Italy rising to great power and affluence.

Let us give our attention to the political situation at that time. I have already shown how the advancement made in textile production by some countries was due to political causes, and how artistic taste was affected by the same events.

The first town of the Italian continent to produce textiles of any importance was Lucca. It is mentioned in this connection in a manuscript so early as 1248. Manufacturing was carried on there to a large extent; the citizens despatched their products to Paris, Bruges and London. But commerce and industry were soon interrupted by civil wars of a sanguinary character. Owing to this cause many clever workmen quitted Lucca and settled in the neighbouring towns; Milan, Florence, Bologna, Venice and Genoa offered refuge to these fugitives and laid claim to their skill.

The many difficulties which had to be overcome in the introduction of this complicated industry, such as obtaining of raw material and the technicalities of weaving and dyeing, gave no opportunity at the commencement for the creation of new patterns. The draughtsmen of the Italian towns, like those of Sicily, seem to have thought themselves bound to follow the style hitherto in use, brought by the Saracens, of figuring parrots and peacocks, gazelles and cheetahs. Therefore it is difficult to say for certain to which place of manufacture the patterns of this period belong, and it is not until the middle of the fourteenth century that the differences in style appear more obvious owing to the advent of the new Italian ornament. It is true that the Italians used the Saracenic designs, but they paid no attention to their symbolical meanings; they thought it sufficient, by copying animal figures and borders bearing inscriptions and floral ornaments, to imitate similar designs upon the Saracenic weavings, which were valued so highly at that time. They would take a group of animals at random, surround it with secondary ornamental work and add to this examples of their own style of ornament. Thus we see animals and plants mingled together with fantastic forms, cartouches, scutcheons, crowns, castles, fences, fluttering ribbons and so forth. In some cases the designs upon the Italian fabrics of the fourteenth century also admit of a symbolical interpretation.

That brilliant fabrics, with their splendid and interesting designs, influenced the poetical art of that time and the songs of the German minstrels is proved by the fact that in the lay of the Nibelungs the description of splendid garments occupies the seventh part of it. In the *epopee Parzival*, by Wolfram Eschenbach, there are high-flown descriptions of a great number of delightfully patterned weavings, with details of their names and origin.

But, on the other hand, songs and legends have also given inspiration for interesting designs. One pattern shows a maiden standing on the battlement of a castle, and holding with her hand a falcon endeavouring to fly. In another pattern we see a maiden coming out of a large flower, on her hand a falcon with bells on its feet, and by her side a dog fastened with a cord.

In the further development of textile designs the slender and graceful tendrils were converted into knotty branches forming a pointed oval, in the middle of which was placed a group of animals in the Saracenic style. The characteristic ornament of the fifteenth century, the pomegranate, is made to sprout out from one of the angles formed by the contact of the branches. At first the pomegranate is small, and takes a subordinated position, the animal figures being predominant, but later on the size of the pomegranate is increased, and that of the animals diminished more and more.

Before we turn to the fully-developed pomegranate-pattern of the fifteenth century, another class of patterns, belonging to the end of the fourteenth century, may be discussed. Here, again, we have those slender, elegant tendrils, with little leaves covering with profuse growth the ground of the material, and often mingled with little birds, hares, dogs, leopards, stags, elephants, dragons, camels, &c. Owing to the influence of the Gothic style, the round arched leaves gradually disappeared, and the vine-leaf and bunches of grapes often appear as a characteristic floral ornament of this epoch.

At the end of the fourteenth century animal figures disappeared totally from design, and the pomegranate was transformed into the imposing pattern which, during the end of the fourteenth, the whole of the fifteenth, and the first quarter of the sixteenth century was a prominent feature. It is composed of a fruit like ananas or pineapple, placed in a cluster of leaves, from which flowers and leaves are sprouting, the whole being surrounded by ornaments of different kinds. The arrangement is the same in all patterns. The pomegranate is placed

in the centre, as a symbol of Christian love, and is surrounded by blossoms and fruit, the whole being symbolically interpreted to mean that love, by the aid of faith, brings forth the fruit of everlasting life. The rose, with five, six or nine leaves, which surrounds the pineapple, is surmounted by crowns—the reward which charity receives in Paradise. The thorny branches, plaited together, tell us of the crown of thorns, and remind us that only by pain and struggle is the victory gained which brings the crown of eternal life.

A very interesting development of the pomegranate pattern appears about the end of the fifteenth century. Broad ornamented stems take an undulating, upward course, and on either side branches bearing blossoms, leaves and little pomegranates are disposed. They were the fashion of the Burgundian court in the latter part of the fifteenth century, where the use of an immense mass of material made the employment of these gigantic patterns possible. In the patterns of this time we see ladies dressed in robes of many folds, and with a long train which was looped up and carried on the arm. The noblemen of the court of Charles the Bold were dressed in large gowns, which, on account of their extravagant length, fell to the ground in folds. Even the saints, the figures of biblical history, were represented by the artists of those times as being dressed in the rich velvets and brocades of the Burgundian period. In the large altar picture in the cathedral of Cologne the holy men are marching in the midst of their splendid suites, as though they were Dukes of Burgundy, while the Holy Virgin is depicted in gorgeous festival garments of the Burgundian court. Naturally the expense attending the weaving of such material was immense, and it is not to be wondered at that an author of those times should write about this pomp and luxury in the following terms:—"The nobles are completely enveloped in gold and silver, velvet and silk, and satin and taffeta. They exhaust their mills, their meadows, fields and woods, in short, their revenues, in order to purchase dresses, the gorgeous ornaments upon which, composed of embroideries, laces, tassels, fringes, chains, &c., often considerably surpass the cost of the material."

Although these splendid fabrics were produced in Italy and in the East up to the fourteenth century, we find that in the fourteenth and fifteenth centuries, owing to the emigration of Italian weavers to France, Flanders and Switzerland, the lucrative art of weaving began to obtain gradually firmer footing in these countries also.

In France more especially the kings attempted to attract the weaving artists by means of charters and privileges, and to settle them in the towns of that country. Amongst these towns Lyons took the first place, and rapidly increased, and with its magnificent productions soon became a dangerous competitor with the other manufacturing towns. This was in consequence of the extraordinary favour and protection which these towns enjoyed from the Government. We are told that in the middle of the sixteenth century Lyons gave employment to 17,000 silk-weavers; about the year 1675, to from 25,000 to 30,000; and when at its best, in the latter half of the eighteenth century, to 80,000 persons.

Now let us consider what kind of designs appear on the manufactures of Lyons, Flanders and Italy in the sixteenth century. It has already been shown by examples how the change from one style to another occurred. For instance, the change from the animal patterns to the pomegranate patterns. In the same way we may follow the gradual variations of the latter until at last a new motive displaces this pattern, which, after having fulfilled its task as a link of this connected chain of textile designs, itself gives place to the new order of things. Just as we occasionally find in some of the fully-developed pomegranate patterns small animals, relics of the textile design of the fourteenth century, so we find the new characteristic feature of the sixteenth-century pattern to be the vase in the pomegranate patterns of the fifteenth century. This ornament makes its first appearance in a very modest way, but gradually increasing in size, it finally displaces the pomegranate itself, and maintains its ground for some length of time amid surroundings of the most varied nature. The thorny branches and the rose change into the sharp-pointed oval enclosures of branches or of elegantly-drawn extended leaves, which are united at the point of contact by calyxes, crowns, &c. In the middle of this oval enclosure the vase is placed, and we see the little blossoms and flowers which were derived from the pomegranate, proceeding from the vase. The fabrics which bear these patterns are woven in a very splendid manner. They are for the most part brocades, with a ground of red satin. The design is formed by a yellow and white woof, which is joined with a warp of red silk in twilled fashion, thus giving a very soft, warm tint to the material. This effect is still more enhanced by a thin strip of silver interwoven with the fabric; this, combined with the yellow and white silk threads, gives a rich metallic lustre, with the changing hues of gold and silver. In several patterns we see alternate rows of vases and pomegranates always enclosed in the same way, or rows of vases without enclosure, and little birds sitting on the branches.

The Renaissance, with its more elegant forms, produced the most varied compositions of the vase pattern.

The great revolution in fashion which followed the introduction of the Spanish styles of dress did not fail to have an effect on the patterning of dresses. The narrow folds and slashings of the garments required small patterns, which merely relieved the ground, but laid no claim to attention on their own account. The tendrils and ribbons, instead of filling large spaces, occupied much smaller ones, in which a small palmetto, derived from the large designs of the fifteenth century, took the place of the large flower vase. The patterns are composed of elegant surroundings, enclosing symmetrical forms, such as the pomegranate or little flower vases, or lastly, little clusters of flowers formed by three or five stalks bearing blossoms and leaves. The colours now are less brilliant. The period of the religious quarrels produced by the Reformation was a more serious one. Men's consciences were awakened, and this earnest time was reflected in the cut and colour of the garments. In velvets especially the subdued tints added a wonderful effect.

During the period of transition from the sixteenth to the seventeenth century the surroundings of little patterns underwent a change, and to some extent disappeared. We can discover the former existence of these surroundings in small branches or parallelograms united diagonally. The calyxes, which formerly united the branches, being separated from them and standing self-dependent, the symmetrical form previously standing in the centre is displaced by an unsymmetrical branch with blossoms and leaves. Finally, the remaining part of the surroundings disappears altogether, and the typical pattern of the beginning of the seventeenth century is complete. It is composed of the unsymmetrical branches, with blossoms and leaves, which appeared in the last variety of surroundings. They are put in series, leaning alternately to the right and left. The style of the drawings and the detail of the plant forms are given with much variety, as well as the size of the branches bearing the flowers, which may be seen from two to ten inches long. This pattern is called "fleurs semées," that is to say, "strewn flowers."

But the more we advance in our researches the greater number of varieties of textile designs we shall meet with. On the whole, greater freedom is to be remarked in the general construction of the designs, as well as in the treatment of the simple forms, which approach more and more a realistic conception. Under the influence of the baroque and rococo styles with their caprices, which disregarded a distinct and constructive arrangement of patterns, the originality, which was periodically common to the patterns of former times, is lost. We see a multitude of designs, which are somewhat alike one another in their character, but of which we miss the common motive, which used to be continually repeated in the former designs, as, for example, the pomegranate in each pattern of the fifteenth century.

The important lace manufacture, which flourished in France more particularly under the Minister Colbert, in the latter half of the seventeenth century, introduced a variety of very splendid woven designs. They are composed of flowery ornaments, spreading out in the shape of a fan, and intersected by interwoven ribbons of lace, very cleverly imitated. The so-called "lace patterns" betray the brilliancy and luxury of the time of Louis XIII. and XIV.

With regard to their technique the velvets of this period are very interesting. The ground is uncut velvet, and the patterns are shown by the cut velvet, and are surrounded by an outline of uncut velvet somewhat higher than the ground velvet. On the velvet of the fifteenth century cut velvet of two different heights appears on one fabric, and in the stuffs of the sixteenth century we learn the difference between the cut and uncut velvet, requiring for its manufacture three different rods: one rod for cut velvet, and two rods of different sizes for the uncut velvet of the ground and of the outline. This fact is a remarkable one.

Besides these fabrics, which only show small patterns in consequence of the narrow Spanish costume which was worn all over Europe at this period, fabrics with large patterns were manufactured for hangings. These materials preserved their symmetrical character for a much longer time than did dress fabrics. We find the vase appearing also in these designs often of a large size, and surrounded by graceful tendrils, frequently filled with birds and quadrupeds and baskets of flowers. Horns of plenty, with surrounding fruit, take the place of the vase in some instances.

Other motives, having their origin in far Eastern Asia, appear in the reign of Louis XV. About the year 1720 Louis XV. sent an extraordinary embassy to the Chinese Emperor, bearing valuable presents and under instructions to co-operate in trade relations, and to revive such as already existed. In return for this politeness, the Chinese Emperor selected splendid presents for the King of France, composed chiefly of beautiful pieces of porcelain, lavishly decorated with Chinese figures and ornaments. This occurrence rendered Chinese style fashion-

able in the upper circles of France for a short time, and the originality of this distant nation in their style of ornament appeared in the textile designs of this period—Chinese vases, the characteristic dragon, landscapes with the curious Chinese perspective, pig-tailed sons of the Chinese empire in boats, and so on.

Contemporary with these patterns after Chinese style, a noteworthy feature was the use of plant forms drawn from nature. Flowers and leaves are rendered with the full effect of light and shade, and the natural colours of the flowers are imitated. The rose is used for choice, but fruit also, cherries and plums; in fact a profuse flora in all possible fantastic forms, together with parts of architecture, cascades, shells, rocks, &c., served as models for the textile patterns of this time. A very good effect was produced by supporting the many-coloured floral ornament by a fanciful ornament woven in gold thread, by means of which the whole composition acquires a peculiar silhouette effect. Textile design has here reached its highest point, both in a capricious choice of motive, in combinations of brilliant colours and in the richness of the bindings.

In the time of Louis XVI. these grand designs, admirable notwithstanding their quaintness, disappeared and gave place to patterns which, as regards delicacy of composition and softness of colour, leave nothing to be wished. The large bunches of roses are diminished to very small elegant nosegays shown upon a white ground with narrow stripes. The colours are reduced to such an extent that they no longer remind us of the preceding luxurious and splendid coloured ornamentation. These small patterns are intermingled with a variety of hunting, fishing, music and such like symbols; fluttering ribbons, festoons, fruit baskets, &c., appear in the intervening spaces. They are the reflection of a period when ruin was approaching and when no energetic effort was possible. The designs on the textiles are a faithful mirror of the trivial social life of that time. But this state of things did not last for long. Probably in consequence of the excavations at Herculaneum and Pompeii motives were furnished for woven designs, which were taken from the wall-paintings of Classic antiquity. They bring us, after the desolation which the French Revolution spread over art, science, industry and trade, to the style of the first French Empire, which found its opportunity in the imitation of the antique.

Thus having brought before you the changes of pattern and style from the earliest days to the beginning of the present century, I discontinue my researches. If we examine the rich collections of antique woven fabrics, which now are established in many towns, we shall be astonished by the manner in which our forefathers could produce wonderful effects with very insufficient mechanical assistance. And now the problem is left us of studying the rich treasures hoarded up in textile museums, and of making use of them for the textile industry, which, as we have already seen, is so very important to the welfare of entire countries and towns.

To encourage all these endeavours, and to bring to notice all the beautiful and interesting subjects for investigation which this subject offers, these remarks have been made; but they do not in any way pretend to have dealt exhaustively with such a very extensive subject.

THE GLASGOW SCHOOL OF ART.

A REPORT has been prepared by a deputation consisting, among others, of Messrs. Burnet, Leiper and Salmon, architects, and Mr. Newbery, head-master, that visited Manchester, Birmingham and London, with the object of ascertaining to what extent technical education could be promoted in the Glasgow School of Art.

They state that in Manchester the passing of the Technical Instruction Act, 1891, decided the City Council to assume the duties and responsibilities set forth in the provisions of the Act. To carry out this purpose a technical instruction committee was formed. Under the Act the Council have power to call up the penny rate for technical education to the full extent. This yields about 11,000*l.*, but so far the draft upon the rates has been slight, the money mainly coming from the funds arising from the Local Taxation (Customs and Excise) Acts of 1891. These funds yielded last year a revenue of 14,300*l.* Of the moneys so received the School of Art was granted last year a sum of 750*l.* and the Technical School 4,000*l.* Designs for a new municipal technical school have been accepted by the City Council, and powers have been sought to raise 150,000*l.*, which covers the estimated cost of the school. This sum will be borrowed on the security of the rates. All fees and all grants from the Science and Art Department pertaining to either school are paid into the common fund, and the teachers' salaries are not regulated by Government grants. Upon the invitation of the School Board, a visit was paid to the Central Board school, Deansgate, Manchester. The School Board does not undertake higher art education. The Art Galleries built in 1825, and then known as the Royal Institution, were handed over to the City Council in 1883, and formally opened as the

City Art Gallery. The annual exhibition of pictures is thrown open to the public on the last two Sundays of the year, and a catalogue is then provided gratuitously by the committee.

In Birmingham, as in Manchester, a central school of art, with fourteen branches; a technical school, the art galleries and museum, and a museum and gallery at Aston Hall, are directly controlled and supported by the Corporation. Certain gentlemen undertook to give land and build a school of art on condition that the town should take over the school when built and carry on its work. The offer was accepted, and the result is that the Central School of Art, Margaret Street, is one of the finest, and certainly the best-equipped school in the three kingdoms. Its success has been so great that a large extension for technical instruction in art, costing 16,000*l.*, has been found necessary. Emanating from it, and governed by its headmaster, are fourteen branch evening schools—one held in a special building, and thirteen held at a nominal rent in the rooms of Board schools. The School Board does not undertake any art teaching in evening classes. The technical school is directly controlled by the Corporation, who have recently purchased a site, at a cost of 12,388*l.*, for the erection of a new building. The Municipal School of Art (central and branch schools), the Museum and Art Gallery, and Aston Hall, are supported under the Birmingham Corporation (Consolidation) Act, 1883, which, amongst many other things, extends the powers conferred by the ordinary free libraries legislation. The Corporation of Birmingham have under their Act unlimited rating powers. As a matter of fact, however, the Art Gallery, Museum, School of Art and art classes combined have not until this year required as much as one penny in the pound. One penny in the pound over the rateable area of the city realises 8,500*l.* The moneys arising from the Customs and Excise duties are estimated for the current year at 13,000*l.* The committee of the School of Art reports in the month of April. The fees, grants, &c., amount this year to 5,724*l.*, which, with 5,699*l.* applied for and granted, makes a total of 11,423*l.* as the estimated cost of carrying on art instruction for the present year. An extremely interesting visit was also made to the Vittoria Street branch school. In this school there is a special room rented by the Jewellers and Silversmiths' Association, in which an experiment is being tried of executing work in the technique of jewellery, such as repoussé, enamelling, chasing, engraving and setting. The present is the third year of the trial, and the experiment seems warranted by the success. In the class of designs chosen, and in the workmanship, an endeavour is being made to interest the student in the production of work of a higher grade than that in which he is engaged during the day.

At South Kensington, General Donnelly, the secretary, and Mr. Thomas Armstrong, the director for art, received the deputation, and put themselves to considerable trouble to assist its objects. The import of the conversation was to the effect that "technical education" could not mean the education of the artisan in art solely with a view to meet the present market demands, but must always be directed to the principles of art as applied to the various industries of the country. The purpose for which schools of art were founded was not to produce designs which should meet the passing needs of the current market or the prevailing fashion, but to educate the designer in the art of design. The authorities would in every way encourage and assist the School of Art in Glasgow to promote instruction in such subjects as designs for glass-staining, wood-carving, metal work, pottery, bookbinding, or any other industries of Glasgow and its neighbourhood in which art is an important factor. It was emphasised that such instruction, however, should strictly be confined to students who had shown satisfactory proof of their powers in the advanced subjects of an art school curriculum. These technical classes should be conducted by artist craftsmen in each speciality. The deputation was to learn what was being done in the art schools of Manchester and Birmingham, particularly in the matter of technical education as applied to art. The information gathered is of considerable value, and what was seen cannot but encourage the governors to press forward the work of the school with greater confidence on the present lines. Although at present we may consider the Glasgow School of Art is doing work equal to that done by the art schools of Manchester and Birmingham, it is far behind these schools in matters both of accommodation and monetary aid. The main efforts must be as at present directed to a purely art education of the highest order, and this should be supplemented by an application of the education thus gained to the various crafts and manufactures of the city. Three facts stand out prominently. (1) That the industrial leaders both of Manchester and Birmingham are fully alive to the benefits to be derived from raising the artistic appreciation and reputation of their respective cities, and realise that this can best be done by collecting and exhibiting the highest art work produced in each craft, and by encouraging the study of the same both in their art schools and by the public generally. (2) That the municipal authorities of these places appreciate these necessities, and are giving liberal

support to art and technical instruction; and (3) that they are entirely devoting the moneys received under the Customs and Excise Act, 1891, to the furtherance of these objects. To these may be added that in Birmingham a thoroughly satisfactory organisation has been built up, under the control and responsibility of the Corporation, whereby under the Birmingham Consolidation Act the overlapping of different agencies is avoided, unnecessary competition is checked, and needless expenditure, both of teaching power and money, is prevented. The deputation think they have exhausted their commission in obtaining and placing before the governors and others interested definite information of the matters set forth in the foregoing report. The conditions of every city are so dissimilar that they do not think it would be advisable for them at present to formulate suggestions based on the report.

DUNBLANE CATHEDRAL.

THE restoration of Dunblane Cathedral is approaching completion. The restored cathedral, says the *Scotsman*, is a beautiful building, conserving, as it does, all the fine features of the old work, and in whatever there is that is new in it showing a skilful harmony between ancient and modern, which exhibits the skill and artistic taste of the architect. For the restoration the country is chiefly indebted to Mrs. Wallace, of Glassingal, a member of the Baird family, who originated the programme, and who has supplied the bulk of the funds—amounting, it is understood, to over 20,000*l.*—for this pious work. The other contribution was 3,500*l.* received from the heritors, who, had the restoration not proceeded, would, it was understood, have been at that expense in building a new parish church, and the cost of the east window, about 700*l.*, was defrayed by Sir John Stirling Maxwell, Bart., of Pollok. The whole of the work has been carried out under the superintendence of Dr. Rowand Anderson, architect, Edinburgh.

Dunblane Cathedral has a chequered history. It occupies a site which has been intimately associated with Christianity since its introduction into Scotland. In the end of the sixth or beginning of the seventh century tradition has it that Blaán, who was of the royal race of the Dalriads of Ulster, founded a small monastic fraternity of the Culdees here, and probably exercised over them the function of abbot or bishop. Then the record is blank for several centuries. In the twelfth century the See fell under the feudatory influence of Gilbert, Bishop of Strathearn; but the handsome endowments he gave it seem to have been wasted, for in 1233, when Bishop Clement came upon the scene, he, we are told, found a roofless church wherein a rustic chaplain said mass thrice a week. He and the Bishop of Glasgow were ordered from Rome by Pope Gregory to levy a tax on all their parishes for the restoration of Dunblane—the alternative being the translation of the site to Inchaffry. The tax seems to have yielded what was expected of it, and Bishop Clement proceeded to build the cathedral very much as it has come down to the present day—demolishing the Romanesque Culdean church, and leaving only the tower, which is now incorporated in the south wall of the nave.

The cathedral consists of a choir, 80 feet long by 28 feet wide, having on the north side of it a long aisle-like apartment of two floors, the lower of which is vaulted; the nave, with north and south aisles, 129 feet long and 58 feet broad, and divided into eight bays, a peculiarity of which is that no two of them are of the same size. There is also the old tower already referred to, which rises on the south side opposite the fifth bay, counting from the west, and is 22 feet square and 97 feet high, surmounted by a slated spire 20 feet high. The building is, with the exception of the lower two-thirds of the tower, of the period of Bishop Clement, who, as already said, flourished in the middle of the thirteenth century. The excepted part of the tower belongs to the eleventh or early part of the twelfth century. The upper third of the tower is assigned to the end of the fifteenth century. The two west divisions of the north aisle, with rather clumsily constructed square-headed windows, belong to a very late period, and the architect, wishing the building to tell as much as possible the story of its construction and successive repairs, left them as he found them. The cathedral, as is well known, has long been famous for the elegance of the great windows in the east and west gables, and there is the "Vesica" window in the apex of the west gable which has been immortalised by Ruskin in his Edinburgh lectures. Ruskin has said that he knows nothing so perfect in its simplicity as the west window of Dunblane. There being no vaulting to the nave, there is no triforium. The clerestory comes immediately above the nave arches. There is a passage in the thickness of the wall, the inside face of which consists of a series of moulded arches, two to each nave arch, and the outside window face corresponds with the inside one. The chancel arch is not of great height. Over it is a double-arched opening, which puzzled experts greatly. There is a passage in

the thickness of this wall, also with access to it from the clerestory passage; and the Marquis of Bute, who has taken great interest in the restoration, suggested that the arched opening might have been used for the display of relics to the worshippers in the nave. The discovery by the architect in the ashlar facing of the wall of holes for receiving the struts for supporting a gallery seems to corroborate this view.

The nave had been unroofed in the Reformation times, and was rapidly going to decay when the restoration scheme was commenced. In the *Scotimonasticum* it is related that in 1559 the Prior of St. Andrews, who had joined the Earl of Argyll with 300 burgesses of Perth, entered the nave during service. While Bishop Chisholm parleyed with them, his congregation melted away. They sacked the chapels, and tore down the woodwork, which they burned, throwing the ornaments into the stream below. In a short time the destruction was complete. After 1564 the church was served by Protestant ministers—the first being one Andrew Graham, a “a preacher of the Word of God.” Thenceforth the building seems to have been much neglected. As to the choir, it is stated in the Statistical Account of 1793 that “the original ‘Popish roof’ is still on the choir, very old and not deemed safe.” This roof was removed in 1860. Several other alterations were made in the year 1818, with a view to rendering the choir a more convenient place of worship. At that time the tracery in the great east window and in the six windows in the south wall of the choir was replaced by perpendicular tracery of an incongruous kind with transoms. The tracery in these windows was replaced in the present restoration by tracery of a more suitable style. Repairs and alterations were also effected upon it in 1870.

In the restoration the architect has repaired and removed only where structurally necessary. Where the old work was sound, although chipped and superficially decayed, he has left it alone. The wall-heads having been repaired, new oak roofs on nave and aisles were put on, and under the protection these afforded the minor repairs were effected. These consisted chiefly of cutting out parts that could no longer hold together and repairing them with sound and new stone, repairing the gable-tops and skewes, making good the rybats of the windows where they were so decayed that they could not be glazed, and repairing the walls where there appeared any signs of weakness.

The nave having been dealt with, the choir, which had been used as the parish church, was then vacated. Here also a new oak roof was put on, and the partition wall that had been erected in the chancel arch was removed. The wall heads were dealt with as in the nave, and the window tracery was renewed. Before the soil and vegetation on the area of the nave and aisles were removed, a careful plan for preservation was made showing all the graves. The whole area was then concreted and asphalted—the finished floor of the nave being a stone one, and composed of red, yellow and black freestone laid in various patterns with excellent effect. The floor of the choir is of tiles and marble; and here have been placed part of the original oaken stalls of the old cathedral—the only things that escaped the hands of the wreckers at the time of the destruction of the sacred edifice already referred to. Divine service has been conducted in the nave of the restored cathedral for some time past, but the choir restorations are not quite finished. The organ case and fittings are in hand, and it is hoped the formal opening of the restored edifice will take place during the summer.

Several exceedingly interesting monuments have been dealt with in the course of the restoration. The founders’ arch was discovered and restored in the north wall of the choir, and in it has now been placed an effigy which tradition said was that of Bishop Dermoch, but which there is reason to believe is no other than that of Bishop Clement, the builder of the cathedral. Among the other effigies are those of a knight in armour and his lady. It was said to be the second Earl of Stratherne, who died in 1271; but the character of the armour and dress points to an earlier period, and it is believed on such evidence that the knight is Gilbert, first Earl of Stratherne, who founded the See and endowed it so richly in the early part of the thirteenth century. There is also in the nave another sepulchral niche and effigy traditionally known as Bishop Ochiltree’s, but the figure evidently does not belong to the niche, as the feet have been cut away to make it fit. There are also the remains of the Strathallan tomb, a work of the seventeenth century of no great interest. Among the more interesting monuments are three blue stone slabs—the matrices of brasses which had been placed there to the memory of Margaret Drummond and her sisters Euphemia (Lady Fleming) and Sybilla Drummond, who came by a tragic end at Drummond Castle in 1502. With Margaret Drummond—who is described as a lady of rare perfections and singular beauty—James IV. fell deeply in love, and made her a promise of marriage. But for political reasons the nobles wished the young king to marry a daughter of Henry VII., and the clergy also forbade the alliance as being within the forbidden degree of consanguinity. As the king was obdurate his mistress’s death was resolved upon, and this was effected by means of poison mixed with food served up at a

breakfast to which she had invited her two sisters. They perished with her, and the three sisters were interred in the chancel of the cathedral. It is gratifying to know that it is proposed to replace these brasses, though without attempting to reproduce the originals, of which no record remains.

It only remains to add that the restored cathedral has been transferred by the Government from the care of the Board of Works to that of the Board of Manufacturers—an eminently suitable body for the custody of this and similar ancient buildings—embracing, as it does, men of antiquarian knowledge and artistic taste.

GENERAL.

Messrs. Richardson, Ellison & Co. are the makers of the wrought-iron gates and railing for the Imperial Institute, according to the designs of Mr. Thomas E. Colcutt, architect. The whole of the wrought-iron grilles for the window openings and finials, as well as the polished brass guards for the post-office and waiting-room on the first floor corridor, were also made by the firm. This metal-work possesses remarkable interest, and should not be overlooked by all visitors to the Institute.

Mr. E. A. Grüning has been appointed arbitrator to settle the dispute between Mr. Charles Wall and the London School Board. Compensation is claimed for increased cost in executing and superintending the works at a school in Fulham, which, it is alleged, threw work that should have been done in fine weather into winter, when the short days greatly enhanced the cost of execution.

The Edinburgh Architectural Association will to-morrow (Saturday) pay a visit to Nunraw, by permission of Mr. W. W. Gray. Nunraw Castle is a specimen of the Scottish baronial style. The oldest part was erected in the thirteenth century, and formed an appanage of the Nunnery at Had-dington, and possesses interesting ceilings, armorial bearings, carvings, &c.

The Comte H. Delaborde has prepared a book on the building where the sections of the Institut meet in Paris. It is called “*Origine et Destinations successives du Palais actuel de l’Institut*.”

The Committee of the Meissonier Exhibition, in Paris, have handed over 25,000 francs to the Night Asylum Charity; 12,500 francs for the Victims of Duty, and 12,500 francs for the Orphanage of the Arts, or in all 2,000*l*.

The Candidates for a chair in the Académie des Beaux-Arts, vacated by the death of Cabat, the landscapist, are the painters, MM. Joseph Blanc, Benjamin Constant, De Curzon, Harpignies, Maillart, Aimé Morot.

Mr. George Pownall, who for many years was a prominent surveyor and valuer in London, died on Sunday last in his eighty-fifth year.

An Arts and Crafts Exhibition will be held at the New Gallery about October next.

Mr. J. W. Trounson, Penzance, has been appointed architect for the renovation and enlargement of the High Street Bible Christian Chapel, Penzance.

The Surveyors’ Institution will meet on Monday, the 8th inst., when a discussion will take place on Mr. R. F. Grantham’s paper, entitled “Recent Experience in Sewage Filtration considered in Relation to River Pollution.”

The Clerestory of the nave of Holy Cross Abbey Church, Shrewsbury, is to be rebuilt under the direction of Mr. J. L. Pearson, R.A.

Professor Flinders Petrie will read a paper on Primitive Art in Egypt before the Applied Art Section of the Society of Arts on Tuesday next.

The Institute of Painters in Water-Colours have elected Messrs. Lucien Davis, H. M. Rheam and Leslie Thomson as members.

The Council of the Whitworth Institute arranged for the summer exhibition to be opened on Wednesday, May 3. It will continue open every day except Friday, from 9 o’clock till 5, and on Sundays from 2 to 5 P.M. The scheme of the exhibition is historical, and it will consist of water-colour drawings, with the addition of such oil-paintings as have been bought out of the Jubilee Exhibition grant of 20,000*l*. and have been given or lent; and of a series of engravings of notable pictures which appeared in that exhibition.

The Late Earl of Derby has bequeathed 2,000*l*. for the purchase of pictures for the Walker Art Gallery, Liverpool, the interest to be devoted to the encouragement of rising artists, and to the Liverpool Museum a cabinet containing minerals and antiquities in his lordship’s house at St. James’s Square.

A New Church is to be erected at Hexthorpe, near Doncaster, to cost 4,560*l*., the whole of the cost being met by Lord Grimthorpe and his sister, Miss Augusta Beckett-Denison, of The Hall, Doncaster.

The Crypt of St. Mark’s, Venice, which dates from the eleventh century, is now illuminated by means of electricity, and was opened to the public on the festival of the patron saint. The ninth-century crypt is still kept closed.

The Architect.

THE WEEK.

WHAT MONTAIGNE says of his family might be used to describe the spirit which inspired the last Academy election. Both sought after something "sans éclat et sans tumulte," were "particulièrement ambitieuse de preud'homme." Four additions have been made to the party that believes so steadfastly in standing still. Mr. HENRY MOORE, it may be assumed, will continue to give the bluest waves, regardless of the difficulty he imposes of discovering any reason for the repetitions. Mr. MACWHIRTER can consider he has obtained a sort of patent for the perpetual production of a couple of favourite trees. Mr. HENRY WOODS need not exert himself more earnestly than he has done since he was enrolled as an Associate. In fact, the three artists, as well as their supporters, may now rest, and it is for the public to be thankful for possessing such Academicians. Mr. J. W. NORTH is no doubt superior to many of the landscapists who can append the letters R.A. to their names that are assumed to be the evidence of excellence, but having hit upon one aspect of country scenes, he remains so faithful to it, we suppose it was assumed that his russets would be as perpetual as Mr. MOORE'S blues, and therefore he was the most eligible for an associateship. The President may talk in his blandest manner about his sympathy with those who are seeking after something that is not stereotyped, but it is evident that he is not able to persuade the prudent men who are around him. They find that the sort of work which is most convenient to produce is "sans éclat et sans tumulte," and when they are so comfortable, why should disturbing forces be introduced among them? The contributions of the majority of the Academicians to each new exhibition prove that pictures at least are coming nearer to an uniform standard, and the latest additions will not need much training to co-operate in the endeavours to reach it. People who are simple enough to imagine that art is or can be made progressive will be disappointed, but the spirit that animates the Academy ought to be known to them before now.

THE decision which was given in the Queen's Bench Division on Monday, in *GALE v. HARVEY* and others, should be taken as a warning by intending tenants who are desirous to have security against expenses incurred through defective drains. A widow lady took a house at Southbourne, Hampshire. Apparently she did not employ an agent in the transaction. She asked the landlord before signing the agreement whether the drains were "all right." He replied in the affirmative, whereupon she signed the document. During the tenancy her daughter fell ill, and the illness was ascribed to defective drains. An action was taken in the County Court, claiming 50% damages for medical expenses, &c. In defence it was said that the landlord had grounds for believing that the drainage was in an efficient state, and there could be no doubt that there was at least a partial overhauling of the drains. Whether there was any guarantee about them in the agreement could not be discovered, for the document was mislaid and the tenant did not appear to possess a copy. However, the County Court judge, accepting the tenant's statement, declared that the expenses arose out of the insanitary condition of the drains, and gave judgment for the 50% claimed. The landlord appealed. The Queen's Bench Division set aside the judgment for the tenant on the ground that there was no evidence of a guarantee of drainage forthcoming. It was the plaintiff's business to prove a contract, and there was nothing to compensate for the absence of a written document. As it was not plain that the tenant did not contribute to making the drains defective there could be no charge of fraud maintained. The conclusions to be drawn from the case are, first, that guarantees of sanitation must be in writing, and, secondly, that ladies will find it safer to employ agents of experience to conduct the negotiations when they are desirous to rent houses.

SINCE the German Parliament has not been as tractable as was desired, the Emperor cannot feel kindly disposed towards it. But that is no reason why the architect of the Parliament House should be compelled to endure the force of imperial irritation. His Majesty has declared the building to be the acme of tastelessness (*den Gipfel der Geschmacklosigkeit*), a phrase which will gratify Sir WILLIAM HARCOURT, since he believes that the power to design public buildings is becoming weaker and weaker. Now, in justice to Herr WALLOT, who designed the new Parliament House, it must be allowed that he was tied down to a fixed plan, which represented the labours of members as well as officials and experts. His suggestions about deviations from it were disregarded, and he was made to feel that his business was to make a sort of skeleton assume a presentable form. When the difficulties of that sort of commission are remembered, all persons (especially any who have had even the slightest experience of dealing with German bureaux) will allow that Herr WALLOT has exercised much skill. That he gained his position in a competition is evidence that he did not take the authorities unawares. The building was also erected under the scrutiny of those who were to use it, and the fact that the position of the Chamber was determined by Prince BISMARCK to suit his convenience suggests the extent of the architect's authority. It is characteristic of the Emperor that he contemplates the ordering of a new course of training for architects as a consequence of his dissatisfaction. Although there is probably not one German architect in practice who has not studied in Italy, it is likely that hereafter every one who aspires to have a part in the erection of public buildings will have to give proofs that he has gone through a long and serious course of study in Rome. At present it might be said that the defects of modern German, or rather Prussian, buildings arise from an overgrowth of knowledge. They are as exact in their details as if they were casts of old works. It would be difficult in one of the suburban villas of Berlin to find a straight line or a curved line, an ornament or a piece of sculpture, that is not rigorously exact. It might be supposed designers and artificers were controlled by efficient drill sergeants. But in architecture something else besides correctness is needed, and the Emperor is likely to find that it is not to be attained by insisting on its presence.

THE Master Builders' Association have taken action in the strike that has begun at Hanley. The joiners who are responsible for initiating the disturbance proposed that six masters and six employes should settle all disputes without reference to an umpire. The masters say that the present strike is proof that this plan is unworkable, for six masters and six men have already met; they could not agree, and a strike is the result. The masters refuse entirely to agree to the proposed rule that they shall not use imported joinery. This rule interferes with their liberty and manner of conducting their business, and is opposed to the principle of free trade. When in England machine-made goods of any kind from abroad can be refused, it will then be time for the joiners to ask for a rule of this kind. As regards apprentices the masters contend that if a master could have one apprentice to every five men it would be possible for a master employing thirty men to have bound to him six apprentices. Then if trade became slack, and he had to reduce his men to six, he would still have to keep the apprentices, and would have an equal number of men and boys. The proposal would, therefore, be a disadvantage for the men. The masters have conceded to the men the hour which they desire on Saturday—that they shall leave work at twelve o'clock instead of one o'clock—at a great inconvenience and loss to themselves. All men who are paid by the day, such as apprentices, clerks and carters, would have to be paid for this hour without any equivalent. Large orders for joinery usually made in the Pottery towns are being sent away to be executed elsewhere. In this case there is no doubt that the masters have right on their side.

PAINTING AT THE ROYAL ACADEMY.

WHEN we find Mr. SOLOMON and Mr. BRAMLEY painting festive birthday scenes (for it is the younger artists who of late give character to Academy exhibitions) instead of classic and seaside tragedies, and that Mr. HACKER tries his hand on nudities in a sun-lighted field, it may be inferred that a great many pictures of pleasant scenes are to be found this year on the walls. It ought to be an exhibition which should afford much pleasure to visitors. There are few paintings exhibited which are too deep for the multitude, and there are so many versions of domestic subjects that the exhibition may be taken as essentially English. We can, however, notice only those works which are in some way exceptional.

It is not easy to discriminate between "costume pieces" and what are supposed to be historical paintings in an Academy exhibition. Sir JOHN MILLAIS'S *The Girlhood of St. Theresa*, in the first room, will no doubt be accepted as history. But can anybody imagine that in this sullen little brunette there is the material for a mystic? Would the boy she leads (holding him by a hand that is very badly painted), if a Spaniard, be captivated by an orange? As history the scene excites wonder for the scholarship of English painters, but as a picture of two children of types that the artist had not earlier represented it has interest. The costumes are of costly materials, and there is much gold embroidery on one, but, unless we are mistaken, they were not derived from Avila. Near it is an historical work of another class, *The Wrestlers' Stone Age*, by Mr. STUART G. DAVIS. The subject is a favourite with modern French artists, but they do not forget that most people nowadays know something about evolution. Accordingly while using such models as are at command they take hints from photographic representations of inferior races. With the exception of a little wildness about the heads (and it would not be difficult to change the hair into hyacinthine locks), Mr. DAVIS'S wild men are English townsmen. It might be imagined that he would gladly make use of the chance to show bodies that gained some colour from exposure to the sun; those in the picture are as pale as any seen at a bathing-place.

The *News from the Armada*, by Mr. SEYMOUR LUCAS, in the second room will gratify many visitors, for, in spite of what the artist has suffered, he can still paint as well as ever. The picture, in fact, reveals an increased power of thoughtfulness. It is supposed to illustrate the fact that the loss of the Armada "affected PHILIP so much that he shut himself up in the Escorial and no one dared to speak to him." The king is seen kneeling at a prie-dieu, a long rosary in his hand; but, like CLAUDIUS, if his words fly up his thoughts remain below. He looks not to the altar in front but towards the right, as if he expected intelligence which would revive his hopes. The agitation of his mind is suggested not merely by the nervous face which is not entirely controlled by consciousness of dignity, but by the evident alarm of the few men who are seen in the chapel, and who seem doubtful about the form in which PHILIP'S sense of defeat may express itself. No doubt Mr. LUCAS is aware that, according to some authorities, the king bore the defeat of his fleet with fortitude, and on that account the picture shows more restraint than the words which inspired it would warrant. The execution is excellent. The king has to be isolated, but it was a happy thought to diminish the effect of vacancy by introducing an immense brass candlestick on either side of him. His black dress is also relieved by the embroidered covering of the prie-dieu, and stands out well against the panelling of the walls. As Mr. BRITON RIVIERE has gone to RAWLINSON'S "Ancient Monarchies" for his subject, it may also be taken as historical. The *King's Libation* is a sort of supplement to the Assyrian series of royal sporting scenes which are in the British Museum. In one of them the king is seen standing with a cup in his hand over a conquered bull, and in another over a lion. Mr. BRITON RIVIERE introduces several lions as victims of the royal bow. They are not of the small species seen in the reliefs, nor are they deficient in the shaggy mane. The king does not wear the tiara, his black hair being bound by a simple fillet, and he has left off the cumbrous outer garments with their tasselled fringes. The scene gains by the abandonment of archaeological detail; the pouring of the libation of blood becomes

a serious, if simple, ceremony, for the king ceases as it were to be a demigod and is a mortal before the gods. But kings and courtiers are only secondary figures beside the lions that appear to have gained dignity in death.

It was said before the exhibition opened that the picture of the year was to be Mr. DICKSEE'S *Funeral of a Viking* or Mr. CALDERON'S *Elizabeth Woodville*. Both have very great merit, but may we add that the interest of both is diminished the more often they are seen? As regards the *Viking*, it is partly caused by the difficulty of realising that the scene took place outside a studio. It is not sea-water on which the boat with the body of the old pirate is launched; it is not northern nor any air which makes the torches flame. The general effect is also over-boisterous. Assuming that men believed that the last voyage was to Valhalla, where heroes and valkyries awaited every brave Norseman, it was not in human nature to allow a chief to depart without some regret. The discipline of the Vikings would also compel them to restrain their exultation on such occasions. It must be allowed, however, in justice to the artist, that his work is as difficult as was ever undertaken. To have achieved partial success with a subject of the kind is creditable. Probably one cause of the shortcomings arises from the influence of archæology. It is not difficult to arrive at a knowledge of the costume, arms and ornaments of the Northmen, but as in this country an artist must go through the inquiry without much help, he is apt to over-rate his discoveries. If Mr. DICKSEE could have forgotten that he was to paint a great deal of metal-work until his figures were arranged, his work would probably have been more impressive. Mr. CALDERON does not make costumes or trinkets obtrusive in the *Elizabeth Woodville*. The dress of the queen and courtiers may be considered as of the plainest. The whole picture is treated in a severe manner. The queen is not over-demonstrative in parting with her son, the Duke of YORK; the archbishop, as becomes a womanly old man, evinces subdued plausibility, and the courtiers are only lookers-on. The picture probably corresponds with the mental vision of the majority of ordinary people who read of the parting, but an artist should possess insight enough to give us more. Mr. CALDERON has not been able to do anything which would impart reality to the scene, and with all the care he has exercised his big picture is hardly more vivid than one of the engravings in an illustrated history of England. On the opposite wall is the President's *Rizpah*. This work, like the *Farewell* in the first room, is interesting from the frank display of method. In both rigid lines are brought into contrast with the contours of limbs or with the folds of drapery. The white cloths which the Jewish woman has thrown over her sons are not out of place, and they aid as opposition of form and colour. So far as we remember there is no precedent for so peculiar a disposition of covering, although white stuffs have been repeatedly placed near dead bodies. It is undoubtedly the most daring experiment in the exhibition; but as technique is not generally understood, it may not be appreciated. Variety is also given by introducing a girl among the victims, and enables a warmer colour to be used in the garment. RIZPAH is a dramatic figure, and adapted to the situation.

The *Glass of Wine with Cæsar Borgia*, by the Hon. JOHN COLLIER, deserves all the admiration it has obtained. The story is told in a way everybody can understand, and the *dramatis personæ* in appearance correspond with the general notions about them. A good many painters would accentuate the incident by introducing images or symbols of a religious kind, but it is impressive enough by itself. CÆSAR offers to fill his guest's cup with poisoned wine. The young fellow realises the position in which he is placed. The Pope waits for the *dénouement*, as if he expected there might be some novelty in it. LUCREZIA is *blasé* with tragedy, and hardly condescends to notice the victim. There is consistency throughout, and no excess of action or passion anywhere. If medals are to be relied on, LUCREZIA BORGIA presented a more woebegone aspect (as of one who, like Lady MACBETH, had known what she should not), and ALEXANDER VI. was less intellectual in appearance; but it is allowable occasionally to take liberties with evidence. In the same room Mr. T. R. SPENCE has a painting, *The First Invasion of Rome by the Gauls*. The incident is dramatic, but all artists who

have attempted it imagine there is only one way to treat it, that is by arranging the senators in a row on a curved bench, with PAPIRUS placed at the end, and bringing in the invaders on the left. We should like to see more variety in the arrangement of the figures, and Mr. SPENCE evidently would have given more animation to his line of senators if he did not believe he was constrained by precedent. The *Trial of Joan of Arc*, by Mr. F. ROE, has an unreal appearance. The tribunal in Rouen was not arranged so simply, and did not mean a bishop seated alone with a few monks at a distance. From the reports of the trial it is evident that there was a variety of judges, assessors, reporters and other officials. The painting may, however, be considered more satisfactory than if it were as correct as M. LENEVEU's scenes in the Panthéon of Paris.

There are peaceful and warlike scenes which, if they do not bring the gorgeousness of the East before us, are supposed to reveal to us something that is to be seen there. But the region of black and brown, "the shadow'd livery of the burnish'd sun," is so vast as to have something indefinite about it, and it would therefore be an advantage if painters were a little more precise in their titles. Whereabouts on the map are we to look for the spot whence Mr. LAVERY derived the lithe, if unmuscular, fellows who wear such brilliant red and green garments as we see in his *Moorish Dance*? There is something strange about Mr. BRANGWYN's *Slave Market*, and yet it may represent an ordinary scene in some village that is not remote in Asia or Africa, but the fine colour would become as attractive if we were assured it was painted after a dream. The two pictures may be more interesting, but they have not that appearance of convincing prosiness which Mr. W. C. HORSELY resolutely puts on canvas. Mr. ARMITAGE's *Moslem Doctrinaire* looks like a portrait, but does it represent a hard-featured man who made a journey to Mecca? Mr. JOHN GRIFFITHS's *On the Temple Steps* is unquestionably a genuine scene, for a Londoner could hardly believe that women and children can be as shadowless as "PETER SCHLEMIHL" and yet be happy. Too little use is made of Indian subjects, and this work is therefore welcome. It well deserves its place on the line, for the artist has not evaded any difficulties, and in spite of the mass of white in the building, there is no startling contrast, and the eye can rest on it without becoming tired. *After the Attack on Sherpur*, by Messrs. CLARK & HAMILTON, also appears to have some reality about it, and suggests what war can do in desolating a district. Mr. E. CROFT's *Charge of the 3rd King's Own Light Dragoons, Moodkee*, does not correspond with the traditions of the fight. The Sikhs did not allow victory to be won so easily as appears, but some English battle-painters seem to believe they must represent English troops as if they were Olympians and can conquer by other means than muscle. Lady BUTLER's paintings have been an exception. In the *Camel Corps* of this year the artist has evidently disregarded the necessity of laying on colour for competition's sake. A novel and interesting scene is represented. Looking at it, we must feel the camel is a maligned animal, for it can be disciplined without much sacrifice of its appearance. There is no doubt that in a smaller gallery and surrounded by fewer works, the intrinsic merits of the picture would be more apparent.

The new and old styles of landscape will be suggested without going beyond the first room, by a comparison of Mr. LEADER's and Mr. MURRAY's paintings. *A Hillside Road*, by Mr. LEADER, is so forcible that he must have been thinking of over-mastering all works near him. But as an expression of a scene, how much more impressive is Mr. MURRAY's *Meadow Sweets*, which, although the greens are Frenchy, suggests we have something before us that is derived from one simple spot, and is not made up of parts of several scenes. The *Fir Faggots* also appears as an unconventional picture of very rough ground. Mr. COLIN HUNTER's *Waiting for Low Tide* is sketchy, and would perhaps look better if it were much higher on the wall. *The Old Bridge*, by Mr. E. A. WATERLOW, is as quiet and dull as could be desired, but the masons who built the bridge must have been unwise, for a pier is in the centre of the river. Mr. WYLLIE's *Newbiggin Bay* seems brighter than most sea-pieces, as coming from a hand that so often selects grimy subjects. Mr. J. E. HODGSON's *Rural England* is

elaborately worked up, and apparently it is a view of a real scene; but as it is flanked by an Italian group by Mr. H. WOODS and a brilliant *School Master's Garden* by Mr. MACBETH, it appears flat and monotonous in colour. Mr. BRETT's *Pearly Summer* would serve as a companion to the *Britannia's Realm* of a former exhibition. Mr. W. L. TURNER's *Strength of the Hills* displays much power. The *Orchard in Picardy* and *Loch Marée* will surprise people who think of him only as a cattle-painter. *Evening*, by Mr. M. R. CORBET, is impressive, and Mr. SOMERSCALES's marine piece should not be passed over, however brief is the visit.

Portraiture, as usual, monopolises the greater part of the walls. Sir J. E. MILLAIS's *John Hare, Esq.*, shows imaginative power in other ways besides the brown colour that is spread over the face. As a work of art, Mr. H. BISHOP's *Miss Huppertz* and *Miss Salvesson* on the same wall is of far more importance. This year Sir J. E. MILLAIS is unlucky in his flesh tints. If the *Merry* in the largest gallery came from an outsider, would it be accepted? Mr. J. S. SARGENT's *Lady Agnes* is so capital a piece of work, it is a pity there are not more examples by the artist in the exhibition. The late Mr. PETTIE's *W. B. Greenfield, Esq.*, is a proof of unimpaired powers. Mr. ALMA-TADEMA's *Dr. Joachim* is excellent as regards the head, but the hands appear not so true to nature. The *F. Seymour Haden, Esq.*, by Mr. JACOMB HOOD, may be a posed portrait, but from the skill with which the expression of the moment is recorded, the subject appears far less stiff, obtrusive and uncomfortable than those which are assumed to be taken unawares. Mr. OULESS is as vigorous as ever in his *Sir Charles Tennant*.

INDIAN HANDICRAFTS.*

THE term "manufacture" may be taken as meaning the transformation of an original substance, by the dexterity of manual labour, into articles for the use of man. The motive-power may be the deft fingers of a Dacca damsel or the steam-engine of a cotton-mill, and the article produced may be a pin or a steam-engine, a sheet of paper, a wine-glass or miles of cloth. In each case the process of manufacture has to be gone through; but, as Sir George Birdwood has truly observed, "in Europe the word 'manufacture' has come at last to lose well nigh all trace of its true etymological meaning," and is now generally applied to articles made by machinery. In considering, however, the subject of Indian manufactures, it is impossible to omit a brief examination of the numerous handicrafts and art industries which would not perhaps now come under the ordinary acceptance of the term "manufactures." From time immemorial India has been famous for its productions of this kind. Mechanical labour, aided by a well-trained eye and delicacy of touch—the result, probably, of hereditary instincts—has produced beautiful examples of handicraft. The embroidery and leatherwork of Kattyawar are spoken of by Marco Polo, in the fifteenth century, as "marvellously beautiful things." "The inhabitants," he says, "are good people, and live by their trade and manufactures." At a less remote period, but at a time when communication was not only imperfect, but was accompanied by risk and danger, the spirit of enterprise visited India and opened to the Western world the riches of its art industries. Its metal and ivorywork, its shawls and embroideries, its carpets of cotton-wool and silk, found their way to this country, and "argosies with portly sail" traversed the Western seas. The same patterns and the same designs have existed for years, and in particular localities and amongst different families and castes, and whatever their origin may be they show a genius for composition and arrangement of colour which is the admiration of all lovers of art. "The Indian workman," says Sir George Birdwood, "from the humblest potter to the most cunning embroiderer in blue and purple and scarlet, is not the less a true artist, although he seldom rises above the traditions of his art." It is most desirable that these art industries should be preserved and kept pure and uncontaminated. With the best intentions harm has sometimes been done by attempting to graft Western ideas upon Eastern designs, whereby purity and harmony have been converted into crudeness and deformity. I do not mean to say that East and West may not learn something from each other, but great discrimination and pure taste are necessary for success in the technical instruction given in our Indian schools of art, and it would be well to raise and stimulate this class of employment by encouraging those who show a decided aptitude for art to pursue it in preference to

* From the paper on "The Manufactures of India, their State and Prospects," read by Sir Juland Danvers at a meeting of the Indian Section of the Society of Arts.

quill-driving and book-keeping. The metalwork, the pottery, the inlaid woodwork, the embroidery, exhibit a variation in shape, colour and pattern which have been for years identified with different localities and castes. It is not easy to trace how these industries were first established. In some cases it was probably accidental; in others it was due to the migration of a family of experts from distant parts, and sometimes perhaps to an inventive genius springing up or to suitable material being found in the neighbourhood. Persia was no doubt the source from which many of the artistic devices which characterise Indian workmanship came.

In May 1884 Mr. Baden Powell gave this Society an interesting account of some of the handicrafts and art industries of India, especially those carried on in the Punjab, and described the characteristics of Indian labour in various parts of the country. He showed that some of the work executed could be traced to a Mohammedan origin, while others contained evidence of Hindoo ideas and feelings. He viewed the subject very much from an artistic point of view, and explored a field in which he has personally done much good service. I do not propose to go over the ground which has been so well covered not only by Mr. Baden Powell, but by Sir George Birdwood, Mr. T. N. Mukharji and Mr. Forbes Watson. Nor will it be possible, within the scope of this paper, to do more than notice briefly the principal industries of the kind referred to.

Allusion has been made to the choice fabrics of cotton, silk and wool which centuries ago adorned the houses of the rich in India, and found their way to Europe, but besides this high class of textile products, ordinary articles of clothing were produced from the village spinning-wheels and looms. These home industries have continued from very remote periods, but have during the last fifty years been greatly interfered with by the cheaper cotton goods imported from England. An additional competition has now sprung up in India itself, and it cannot be doubted that the machine-made textiles will gradually cause the hand-made cloths to diminish. This result is of course inevitable in every country where progress is being made. It is said that the fabrics produced by the village looms are of greater strength and better quality than those made by machinery, so that a supply may be continued to those who are ready to pay a higher price for a superior article.

One of the first fabrics weaved from Indian cotton, which will occur to everybody, is muslin. The beauty and lightness of Dacca muslin still holds its pre-eminence, although its sale is now very limited. The fineness of its texture is described by the well-known names of "Evening Dew" and "Woven Air," and is proved by the traditional test of passing twenty yards of it, one yard wide, through a lady's wedding-ring. It has been said that the fingers of the women by whom it is spun are losing their cunning, but a very fine fabric is still made, being used only by the rich and noble. The greater the length and number of threads, and the less the weight of the piece, the higher is the price. The lower qualities, used for turbans, veils and clothing, have generally been superseded by the machine-made article from Europe. The antiquity of Indian muslin is traced far back by Sir George Birdwood, who is of opinion that in the time of the Chaldeans it was carried into Babylonia as a regular article of trade, and that cotton also, in the form of the Arabic tunics, became known to the Greeks before the age of Homer. The word "cotton" does not appear in the Old Testament, but Sir George Birdwood, with his knowledge of Hebrew and Sanskrit, is able to point out the interesting fact that the passage in Esther (chapter i. verse 6) which runs, "Where were white, green and blue hangings fastened with cords of fine linen," should be rightly translated, "Where were white and blue (striped) cotton hangings."

Calico, like muslin, was in times past much thought of in England. It is supposed to have been first introduced from Calicut, from which place it derives its name. Its texture and printed patterns were the admiration of our great-great-grandmothers, and it was much worn for dresses in this country, so much so that it alarmed our silk-weavers, in whose interests a law was passed in 1721 prohibiting the use of printed calicoes. Fifteen years afterwards this was modified so as to admit of their being worn, "provided the warp thereof was entirely of linen." They had their day, but were ultimately superseded by the machine-made stuffs of England, and these have in a great measure also displaced the hand-loom fabric in India itself. A common kind is still made there, and the day may again come when the wheel of fortune will enable it to take a larger place in the Indian market.

Silk has for a long period been made and largely used in India, and in former times silk fabrics were exported to Europe. There has, however, always been difficulty in cultivating the domesticated mulberry-feeding silkworm. More than a century ago the East India Company made efforts to introduce the Italian system; but while improvements were made in the filature the experiments ultimately failed, apparently from the climatic effects upon the mulberry tree, and the silk industry became dependent for its native supply on the

wild insect. The fabric thus produced is known as the Tasar silk. The trade in Indian silk is now small. In his last report Mr. J. E. O'Connor speaks in a desponding tone as to its decadence. "It is clear," he says, "that Indian silk is not able to hold the market: our exports to foreign countries amounted to little more than half the imports." Most of the manufactured article is made from the raw material imported into Bombay and Burma from China and Europe. I would venture to express the hope that the present condition of this industry should not produce despondency, and that it will still be thought worth while to apply skill and science in overcoming the physical difficulties of cultivation.

To pass from silk to embroidery is a short step, silk brocades forming the foundation for some of the most beautiful specimens. Few articles of Indian ware excited more admiration at the various international exhibitions that have taken place than the *kinchâbs*, the horse-trappings, the *kârehobs* and *jémdanis*. It is truly an art industry, brought to perfection by the richness of the material used, as well as by the beauty of the patterns and the harmony of colours. It is surprising that, with our growing love of decorative art and our improving tastes, more of this kind of ornamentation is not seen in our halls and reception-rooms.

Carpets, on the other hand, have found their way into English homes and are very generally used. In former times a specimen here and there, more often in the shape of rugs than full-sized carpets, might have been seen in houses connected by association with the East, but after the exhibitions of 1851 and 1862 a considerable trade was started, and has continued. They are made of cotton-wool, silk, goat's hair, and these materials mixed, and are hand-woven, seamless, and of various sizes. They, of course, vary in quality and price, but, as in most things, the best are the cheapest in the end, from their durability, elasticity and softness. Carpet-making is a large gaol industry, but there are private manufactories in various parts of the country. Competition, and the demand for a cheap article, have not been without ill-effects. Attempts are sometimes made to graft European ideas upon Eastern patterns, and the result is always disastrous. The use of inferior dyes has also become too common. The manufacturer and the customer should be strenuously warned against these injurious processes, and be persuaded that, if the industry is to flourish, its character for pure design and good workmanship must be maintained.

In many places gold and silver are turned into ornaments and into articles of use for the table. While some are beautifully chaste, others are only rudely finished, and are more curious than pretty. In addition to trays, goblets, plates and bowls, the articles peculiar to India are the rose-water sprinklers, hukkas, betel boxes, water vessels, &c. The places most famous for gold and silver work are Cashmere, Lucknow, Cuttack, Rajputana, in Northern India; Ahmedabad and Cutch in the Bombay Presidency; and Dindigal, Madura, Arcot and Cochin in Madras. Burma also has not neglected the art. The work is as various as the places, each having its distinguishing feature. Speaking generally, and comparing Indian with English plate, while recognising the beauty of its form and pattern, there would appear to be a want of finish, and as we know from the sad demolition which often took place when brought into this country, too large an ingredient of alloy. The removal of the import duty, and the regulations with regard to hall-marking will, it may be hoped, not only have the effect of improving its quality, but of increasing the desire to make it as perfect as possible.

Gold and silver ornaments, jewellery and trinkets of all kinds, filigree work and wire-drawing decorations, are made in most towns of India. The love of the native for personal adornment, and the means of hoarding provided by the conversion of the precious metals into ornaments for various parts of the body (the head, nose, ears and ankles), create a local demand which employs a large number of people. Jewellery, like plate, generally needs the finishing touch to bring it up to the European standard, and precious stones are thought more of for their weight than brilliancy. The cutting of gems is thus sparingly exercised, and a polish is considered sufficient. It will be recollected that the *Koh-i-noor* was, after its arrival in this country, on the advice of competent judges, ordered by the Queen to be recut, and that, although reduced in weight from 180 to 102½ carats by the operation, its brilliancy was greatly intensified; and that, in the words of Mr. William Pole, it became "what it never was before, a most splendid jewel, worthy of its royal mistress, whose unsullied diadem may it long adorn."

Brass and copper are largely used for vessels of domestic use, as well as for ornaments and personal decoration. The industry is an important one, and much skill and ingenuity are applied to the work. The Hindoos are said to prefer brass and the Mohammedans tinned copper for their cooking utensils. The Benares brass ware, with its bright shimmering surface, is now well-known in this country. It is said to have been imitated at Birmingham, and that the ignorant and

unwary have been caught by it. The Indian ware is worked out by the skilled artificer, who, with a simple hammer in one hand and a pointed instrument in the other, engraves, without any pattern or tracing before him, the design which is in his head. In Lucknow, Delhi, Moradabad, Amritsir and other towns in the North-West Provinces and the Punjab, as well as places in the Central Provinces, Rajputana, Madras and Bombay, the metal industry is carried on. In fact, all over India the aptitude of the native in this department of industry is exemplified.

There are other crafts, some almost unique in their character, such as enamelling, lacquer-work, inlaid work, stone and wood-carving, ivory-carving, which it is impossible to do justice to in the limited space of this paper. The same may be said of pottery and glass, which have existed from early times and are still pursued. I must refer my hearers to the excellent work of Sir George Birdwood on "The Industrial Arts of India," as well as to Dr. Watt's valuable "Dictionary of Indian Products," and the interesting accounts by Mr. Baden Powell, Mr. J. L. Kipling, Sir Edward Buck, Mr. Purdon Clarke and others of the industries of various districts. To the labours of these gentlemen in the country itself, and to their instructive reports, we owe the knowledge we now possess on the subject, and to the same cause is due the preservation of what is good, and the introduction of improvements in the arts themselves. I would also recommend a visit to the well-arranged collection of specimens of work in the Indian Museum at South Kensington.

It will be seen that the handicrafts above mentioned constitute an important part of the large earning industries of the country. They are important as well for the higher occupation they provide as for the artistic character of the work performed. It is true that imitation more than originality and individuality is brought out, but there is an undeniable charm in the general results produced. What is meritorious should be preserved and made the foundation upon which improved appliances and an instructed intelligence may build a useful and profitable superstructure.

THE NEW PARLIAMENT BUILDINGS OF ONTARIO.

THE new Parliament Buildings at Toronto have been opened. It naturally occurs to us in chronicling the event, says the *Canadian Architect*, to consider what sort of bargain the people of Ontario got for their 1,200,000 dols. odd.

The general scheme seems proper. The Legislative Chamber is in the centre, over the main entrance and approached by the grand staircase. This gives the central motive which, from its singleness of purpose, lends itself to effective composition on the exterior. The offices of the Legislature and of the departments extend on each side of the centre and along wings which return northward, finishing with a stack of lavatories at the end of each. That is the plan in simple, and it seems a straightforward plan in the usual manner of public buildings where a general scheme rules, and rooms are apt to be proportioned by position rather than use. But in the main feature of the interior arrangement there has been a judicious expenditure of space which makes the inside of the building fine, and is worthy of all praise. The grand corridor which runs the entire length of the building from east to west, is made of sufficient width to have on each side of the central portion (where the grand staircase landing intervenes) a space open from the ground floor to a skylight in the roof. The passages of the upper floors thus take the form of galleries at these points, and on the ground floor the corridor has on each side a colonnade which supports these galleries and their arcades. The colonnades, the open space, the light from above, all combine to redeem the corridor from the dark and dreary monotony that is so often all the architectural effect presented by the passages of a great public building.

Thus far we may perhaps assume the architect, but we are afraid it is too obvious that the person with whom we have had to deal for the carrying out of the plan is not so much the architect as the architect's draughtsman. We have no doubt the draughtsman did his best, we would impute to him nothing but righteousness, but surely the architect's commission was sufficient to afford a draughtsman who could design. In this same corridor which we have described there is but one set of columns to be repeated along the whole colonnade. The detailing was limited, and with a little careful study in the hands of one who knew something might have been carried to perfection and made the whole corridor beautiful where now the details are poor on the ground floor and offensive in the upper storeys. On paper this essay of an apprentice in columnar details would be something to smile at, but that they should be actually erected in an important public building is a matter rather for indignation. The same may be said of the grand staircase. It starts fairly well in iron and slate, but above, where we get to the region of arcades, and what we may suppose to be

intended for an ornamental ceiling, the draughtsman's efforts should not have been allowed.

The Assembly Chamber, the grand piece of the design, shows more skill in the designer, but we are afraid cannot be said to satisfy good taste. There is some well executed wood-carving on the floor of the House which really gives pleasure and is of the more value as being different in type from the style we have become accustomed to of late years.

Of the exterior we are afraid there is little good to be said beyond praise of the material. It is a fine mass of Credit Valley brown stone, and as such cannot but look important. It is not, however, of meanness we have to complain. The central pavilion with the main entrance, the 16 feet unmulioned windows of the Legislative Chamber above, and the enormous roof which crowns it, is certainly striking. But its proportions are swaggering rather than dignified. Perhaps its self-assertion may be intended to represent the idea of provincial autonomy, but we must confess we should have preferred to have complimented the idea by representing it with a little more of the dignity of beauty.

The roof of this central pavilion is a fine and bold erection, but it seems to us a pity that it was not constructed of iron, so as to save at least the danger of fire originating within its own limits. As it is, being a forest of timber above the highest cast of the hose, its existence is a menace to the public documents below, and the public may perhaps some day wish it were away. As for the other roofs, we must candidly say we wish they were away now, especially the eccentric hipped roofs with glass tops over the main building on each side of the centre. They must form capacious snow traps at the junction with the other roofs. But our discontent is chiefly with the question of beauty of form, and with the draughtsman's apparent indecision as to what pitch to adopt. If the buildings had been planned for a long ridge instead of these pyramidal forms with glass apexes, the front would have been much helped, and the glass might have shown only on the rear—the long suffering but picturesque rear.

But the glass is a friend giving the top lighted corridors within, and we should have been glad to see more of it if the architect had availed himself of it to a greater extent so as to reduce the size of the windows on the façades. It is these which really spoil the building. They have not even practical advantage to recommend them. The corridors are lighted chiefly from the top, and could be given more light from that quarter and from the rear. For the offices themselves, windows of such a size are a great discomfort. The mere operation of lifting a sheet of glass 9 feet wide is found to be troublesome. In winter the rooms must be pervaded by the sun to a painful extent, and in summer also it will probably be necessary to keep the blinds down and exclude air as well as sun. With windows on a more reasonable scale there is more chance of compact and well arranged planning of the offices, as there is greater freedom offered for the disposition of partitions. The draughtsman too, with more reasonable windows, might have suffered less defeat on the exterior. As it is he has been unable to make anything of it. The conditions were hard, and he does not seem to have been skilful. Where he erred he erred no doubt from ignorance; but this same ignorance, how much has it cost us? Draughtsman is writ large all over our greatest and most costly public building.

THE ART FOR SCHOOLS ASSOCIATION.

THE annual meeting of the Art for Schools Association was held on Monday at the offices, Queen Square, Bloomsbury, Cardinal Vaughan presiding. The Association was founded in 1883 with the object of supplying an educational basis for the work already being done by loan exhibitions of pictures in poor districts of London and other large towns. The idea of the founders was that much might be done to educate and feed the taste of children by simply placing in the classrooms of elementary schools a few good prints and photographs of beautiful and interesting works of art, such as people of taste cared to have in their own houses. The chief work of the Association is to supply elementary schools with works of art at a nominal profit, and a very large number of schools have already availed themselves of the facilities offered. In opening the proceedings, his Eminence stated that the work which had been done by the Society was one of very considerable importance and deserving of a very much wider support than it had hitherto received. In the work of education there were two kinds of influences, the supernatural and the human, and however much people might differ on questions affecting the form of religion, they were mostly agreed that both these influences were essential in the education of youth. Art might be used on both the religious and the profane sides of education, but in either sense it was elevating and refining, provided it was high and worthy art. A debased and sensual art would have a detrimental effect upon the morals of the younger generation, and an ennobling art would have an ennobling effect. He might indeed say, "If you will tell me what is your

art, I will tell you what is your state of civilisation and refinement." The adoption of the report was moved by Mr. Armine Willis, seconded by Mrs. Westlake, and agreed to.

TESSERÆ.

Russian Churches.

THE belfry belonging to the more ancient Russian churches, wherever such a building exists at all, is always insulated and often removed to such a distance from the nave as to appear a totally independent structure. In the course of the seventeenth century, it became customary to place it invariably on the western side, and to connect it with the body of the church (to which its lower storey afforded a species of vestibule) by a passage of moderate length. Thus, by means of this passage and vestibule to the west, and of the sanctuary which projected at the opposite extremity to the east, the ground-plan of the whole building was made to assume the shape of a cross, which was soon modified into a form little differing from that of our cathedrals. The connecting passage was enlarged till it became the most considerable portion of the church. The ancient square nave acquired by this alteration the appearance of a transept, while the sanctuary alone was suffered to retain its former proportions, having never been sufficiently expanded to admit of a comparison with a Latin choir. Evidence of this change may be traced in many of the smaller churches at Moscow, particularly in that near the Kunetskoy Most. During the reign of Peter the Great, Russian church architecture was still further deprived of its original and national character by the general adoption of the classical orders, which became fashionable at that period. The bulbous cupola likewise, though never altogether laid aside, began at the same time to fall into comparative disuse, and was replaced by an overgrown dome of the Italian form, which, being painted green, is, at present, the never-failing head-piece of every modern Russian church. An ancient but tasteless custom was injudiciously retained of degrading the exterior architecture by the application of bright and incongruous colours, which though sufficiently suited to the irregular and barbaric structures of the Muscovite Tsars, but ill accord with the classical elevations of so young a city at St. Petersburg.

Giulio Romano as an Architect.

While St. Peter's was still in progress at Rome, Giulio Romano, the first scholar of Raphael, was employing his great talents as an architect as well as a painter for the ornament of the city of Mantua. No town was ever probably so much indebted to a single individual. The interior of the cathedral is a monument of his genius. This church consists of five aisles, or seven including the side chapels. That in the middle is of two storeys, the lower of fluted and reeded Corinthian columns, the upper of Corinthian pilasters, with the entablatures unbroken. The ceiling of this aisle is flat, of the two on each side of it semicircular, and of the two outer aisles flat again. These side aisles are separated from each other by columns like those of the middle aisles. It has a handsome dome and a handsome chapel with another cupola, but it is not certain that the latter was designed by Giulio Romano. The front of his own house is of a simple and singular architecture, but productive of good effect. He was not free from the affectation of singularity and from a wish to innovate, but his innovations are quite his own; unauthorised by precedent and unadopted by others, though they have injured some of his own buildings they have not been prejudicial to those of others. Some of them are to be seen in the Palazzo del Te, particularly a sort of subsidence in a Doric frieze, which gives it an appearance of weakness, as inconsistent as possible with the character of the order and very displeasing to the eye. There is an arcade in this palace, supported by a sort of pilaster, formed by four Doric columns together, which has an extremely good effect; perhaps he may have been indebted for the idea to the clustered columns of the Gothic architects.

Art and the Artist.

If illusions are necessary to happiness, no folly can be greater than to know both the workman and his work. Yet there is an age for most men when illusions are powerless, and when truth, however harsh, can be reconciled with older truth. The fact is, that the work is both greater and less than the workman. It is less, because no result in this world is as grand as the conception in the author's mind. It is greater, because no mind can conceive a result together with the details that compose it. The work must have details, the mind conceives only the whole. Again, the work often makes the workman. The very first details to which he must descend suggest new ones to which he could never have ascended else. From detail to detail he modifies his first conception, and the very work itself reflects upon his mind, and flashes new lights into it. We will venture to say that no author ever wrote a good book in exactly the manner that he had first planned it, and no good

picture was ever painted to realise accurately the first picture in the artist's mind. The work, then, is often greater than the workman; and hence it is that we are so grievously disappointed when we come to look into the lives and characters of great artists. If this be true for all art—if we find Milton the prejudiced organ of a party, and Shakespeare the hero of the "Mermaid," it is still more true for imitative arts. In these particularly the mind of the workman has a materialist tendency. The difference between the poet and the painter is this, the one ascends from the material to the ideal, the other descends from the ideal to the material. The one robes the things of earth in a heavenly light, the other steals the fire from heaven to show it bodily to men. The one is the lark soaring, the other the lark falling. It is true that you must soar before you can fall, but then you do fall. The clouds will hold the poet, but only the earth will satisfy the artist. Words may combine to form ideas beyond the common associations, but pictures of form can only appeal to the commonest associations.

The Tomb of Mohammed.

The Hujrah, or "Chamber," as it is called, from the circumstance of its having been Ayisha's room, is an irregular square of from 50 to 55 feet in the south-east corner of the building, and separated on all sides from the walls of the mosque by a passage about 26 feet broad on the south side and 20 on the eastern. This isolation is explained by a saying of Mohammed, "O Allah, cause not my tomb to become an object of idolatrous adoration. May Allah's wrath fall heavy upon the people who make the tombs of their prophets places of prayer." Inside there are, or are supposed to be, three tombs facing the south, surrounded by stone walls without any aperture, or, as others say, by strong planking. Whatever this material may be, it is hung outside by a curtain, somewhat like a large four-post bed. The outer railing is separated by a dark narrow passage from the inner one, which it surrounds, and is of iron filigree painted of a vivid grass green, with a view to the garden, whilst carefully inserted in the verdure, and doubly bright by contrast, is the gilt or burnished brasswork forming the long and graceful letters of the Suls character, and disposed into the Moslem creed, the profession of unity and similar religious sentences. On the south side, for greater honour, the railing is plated over with silver, and silver letters are interlaced with it. This fence, which connects the columns and forbids passage to all men, may be compared to the baldacchino of Roman churches. It has four gates: that to the south is the Bab el Muwajjah; eastward is the gate of our Lady Fatimah; westward the Bab el Taubah (of repentance), opening into the Rauzah or garden, and to the north the Bab el Shami or Syrian gate. They are constantly kept closed, except the fourth, which admits, into the dark passage above alluded to, the officers who have charge of the treasures there deposited and the eunuchs who sweep the floor, light the lamps and carry away the presents sometimes thrown in here by devotees. In the southern side of the fence are three windows, holes about half a foot square and placed from 4 to 5 feet above the ground; they are said to be between 3 and 4 cubits from the Prophet's head. The most westerly of these is supposed to front Mohammed's tomb, wherefore it is called the Shubák el Nabi, or the Prophet's window. The next, on the right as you front it, is Abubekr's, and the most easterly of the three is Omar's. Above the Hujrah is the Green Dome, surmounted outside by a large gilt crescent springing from a series of globes. The glowing imaginations of the Moslems crown this gem of the building with a pillar of heavenly light, which directs from three days' distance the pilgrim's steps towards El-Medinah. But, alas! none save holy men (and perhaps odylic sensitives), whose material organs are piercing as their vision is spiritual, are allowed the privilege of beholding this poetic splendour.

Sir Peter Lely.

Captain Van der Faes was born in a house at the sign of the Lily in the town of Soest, in Westphalia, and hence obtained the sobriquet of the Captain of the Lily. So goes the story which accounts for the more graceful synonym of his son Peter. This son was born in 1617, and placed in due course in the studio of Grebber, at Haerlem, where Nicholas Berghem, the landscape painter, and Egbert Hemsckerck, the devil painter, were his fellow students. Lely himself began, like Reubens, with landscape—a study which enabled him to give to his portraits in after life those charmingly unnatural accessories which have remained in fashion in this country almost to this day. Following his master, Lely next turned to historical painting, but was not very successful. The best of his pieces, according to Dr. Waagen, is the "Susanna and the Elders" at Burleigh House. But in 1641 he came to England, and finding that portrait was about the only branch of art patronised here, he turned his attention to that style, for which he has since become so famous. In this country he settled in spite of the civil war, survived the Commonwealth, and charmed the second Charles with the voluptuousness of his female figures. The king employed him to paint—on canvas—his mistresses and

the ladies of his court, in dresses as loose as their characters. Sir Peter made beauties of these frail creatures and gave to each a tender expression of languishing innocence, which in nine cases out of ten must have been pure flattery. But as works of art the contents of the room at Hampton Court are unsurpassed by any female portraits of any other master. Nothing can exceed the softness of the flesh, nothing the grace of attitude, nothing the richness of colouring and freedom of design which these beauties display. Few women are impervious to delicate flattery, and those who graced or disgraced the court of Lely's patron were not among the minority. Sir Peter had therefore no battle of life to fight here, but made a rapid and enormous fortune. He collected a magnificent gallery, partly from the remains of the Arundel and Buckingham collections, which sold after his death for 26,000*l*. He amassed sufficient to leave besides this a landed estate worth 900*l*. a year, though he had always lived well. He died suddenly of apoplexy in 1680, and Gibbons carved the monument which was raised over his remains in Covent Garden. If his proneness to flattery extended to the portrait he painted of himself, he must have been one of the ugliest men of his day. In character he appears generous and liberal, but intensely jealous of other painters, particularly his own pupils, from whom he concealed the most precious secrets of his art.

The Progress of Architecture.

Art, if it be a thing of life, must be in a constant state of advance, whether it be to maturity and excellence or to decrepitude and decay. It cannot have a retrograde movement; the attempt would only be attended with ridicule and failure. Possibly its fate may be retarded for a time; an honourable old age and a glorious death may be insured for it. It may be embalmed with regrets and reverence done to its memory, but it cannot be recalled to life, reproduced as it was, with the same features, nerves and sinews. The phoenix must die and be consumed. A more beautiful offspring may arise from her ashes, and may resemble and remind one of her lost parent; some of her lineaments may be traced, some of her transmitted energies witnessed, but the identity is gone; the new life implies a new individuality. The lost is not restored but succeeded. The generations of man may see hundreds of successive Gothic styles spring and decay, but none of them will be the Gothic of the thirteenth and fourteenth centuries; and they will be attained, not by retracing one's steps and professedly imitating what is past, but by constant progress. Anything that is gained by a retrograde movement will prove to be without life, value or reality. There is a vast difference between the imperfections of a man who is doing his best and constantly striving to do better, and those of one who purposely sets before himself a lower standard than has been reached, and that he knows can be reached. The former is looked upon with indulgence and respect; the latter with contempt. What shows earnestness in the one is a proof of affectation in the other. And therefore the savageness which Mr. Ruskin points to as the first and most characteristic feature of genuine Gothic, and as giving it the true stamp of nobility, is just the one that cannot and must not be attempted to attain unless it be by setting up a higher standard than any hitherto reached, and then the same causes may produce the same effects and still more noble and powerful. If art is progressive an increasing eagerness for perfection must be a necessary and natural condition. An attempt to check it is an attempt to check nature. Unquestionably it contains not only the nourishment of excellence but the germs of decay. It is well known that there is a point beyond which refinement will detract from beauty and power; but if art and society are in a constant state of progress they will not stop at that point: they will either proceed till over-refinement has weakened them beyond power of self support, or else they will transfer their care to some branch which has not yet received it to the same extent. And when these changes have taken place just at the right time and been made just in the right direction, an excellence has been reached little short of supernatural.

Colour Vision.

When we look at a broad field of uniform colour, whether it is really simple or compound, we find that the sensation of colour appears to our consciousness as one and indivisible. We cannot directly recognise the elementary sensations of which it is composed, as we can distinguish the component notes of a musical chord. A colour, therefore, must be regarded as a single thing, the quality of which is capable of variation. To bring a quality within the grasp of exact science, we must conceive it as depending on the values of one or more variable quantities, and the first step in our scientific progress is to determine the number of these variables which are necessary and sufficient to determine the quality of a colour. We do not require any elaborate experiments to prove that the quality of colour can vary in three and only in three independent ways. One way of expressing this is by saying, with the painters, that

colour may vary in hue, tint and shade. The finest example of a series of colours, varying in hue, is the spectrum itself. A difference in hue may be illustrated by the difference between adjoining colours in the spectrum. The series of hues in the spectrum is not complete, for, in order to get purple hues, we must blend the red and the blue. Tint may be defined as the degree of purity of a colour. Thus bright yellow, buff and cream-colour form a series of colours of nearly the same hue, but varying in tint. The tints corresponding to any given hue form a series, beginning with the most pronounced colour, and ending with a perfectly neutral tint. Shade may be defined as the greater or less defect of illumination. If we begin with any tint of any hue, we can form a gradation from that colour to black, and this gradation is a series of shades of that colour. Thus we may say that brown is a dark shade of orange. The quality of a colour may vary in three different and independent ways. We cannot conceive of any others. In fact, if we adjust one colour to another, so as to agree in hue, in tint and in shade, the two colours are absolutely indistinguishable. There are, therefore, three, and only three, ways in which a colour can vary. We may determine the number of quantities upon which the variation of colour depends by means of our ordinary experience alone. If we wish to specify the position of a point in a room, we may do so by giving the measurements of three distances, namely, the height above the floor and the distances from two walls forming an angle. This is only one of many ways of stating the position of a point, but it is one of the most convenient. Now, colour also depends on three things. If we call these the intensities of the three primary colour sensations, and if we are able in any way to measure these three intensities, we may consider the colour as specified by these three measurements. Hence the specification of a colour agrees with the specification of a point in the room in depending on three measurements.

Imitation in Painting.

The experience of every artist has suggested to him the difficulty of defining for himself the true standard or quantity of imitation which should in any given case be employed for the fitting representation of the object or objects which he has in view. At the commencement of his career the student is apt to be influenced by the desire to mark down all particulars which to his eye make up the sum of the thing before him, and as at that age the artist is an almost microscopic observer, a study which might well befit the naturalist becomes in its rendering of specific fact a fatigue to the sense to which it appeals as a work of art. The end is, in fact, missed through the very over-elaboration of the means. It is this habit of seeing too much, through want of taste or of judgment, that makes a portrait painted by a beginner so little satisfactory. Not contented with so much of imitation as shall secure identity with the type, he has insisted on details as punctiliously as a surveyor might, whose task it was to make a chart of the face. He has mistaken a picture for a map. That simplicity, not complication, of means serves the purpose of identification in form is illustrated by a fact in every man's daily experience, the facility with which at a distance or amid a crowd we distinguish a well-known figure or face. In the first of these cases the facts are resolved by the distance; in the second they are generalised by the numbers in which the mere technical particulars are to some extent the same or similar. In both it is shown that the individuality is something outside of or added to the facts, and this it is which the painter has to seize, as by a few expressive lines he often may. To borrow an illustration from the arithmetician, the likeness is the resulting whole which expresses, as it were, in a single line the sum of all the several figures which are its factors, not a precise repetition of all the figures which make up that whole. The process of art-imitation is synthetic, not analytic. The amount of character which a few forms are capable of expressing is well illustrated also in the breadth of treatment and simplicity of means employed for portraiture by the Egyptian sculptor 3,400 years before the Christian era, as well as in some of the historic themes of the same people. The like principle of simple means was eloquently applied to the decoration of the Etruscan vase, a few lines by means of which a variety of condition, age, sex, &c. are expressed and recognised in forms of beauty, of grace or of motion. In the flattest or lowest relief of Greek sculpture everything is almost reduced to outline. Patient investigation and that experience which implies the combination of judgment with taste must be employed to determine in each case, by comparisons with a number of objects in the same class, what are the essential peculiarities that constitute its character, standard or true type. There are certain specific attributes peculiar to each object either in form, in character or in colour, and the central or focal point of these is its essence. Divergence from this constitutes variety—exaggeration of it, caricature. This essential form it is which the artist must seize. When this is expressed in his work the idea of that work is complete.

NOTES AND COMMENTS.

THE Musée Carnavalet in Paris has interest for all lovers of French literature, especially of one period. The house itself was occupied for about twenty years by Madame DE SEVIGNÉ. There is much in it which relates to the seventeenth century, of which she was one of the ornaments. In fact, the Musée at present suffers from overcrowding, and many objects which should be seen there have to be sent elsewhere. With all its shortcomings the Musée Carnavalet is the most fitting place for a stranger to study relics of old Paris. M. COUSIN, the conservator, has formed plans for the extension of the Musée. But the adjoining building, which is in a similar style and could be readily and economically adapted for use, is now to be appropriated for a lycée de jeunes filles. It may, therefore, be assumed that for the present all hope of an extension has vanished. Probably the authorities contemplate the foundation elsewhere of a musée of Paris, ancient and modern, for which the collections could be utilised. But in that case the interest derived from association must be lost.

AMERICA is the land of storms, and the Chicago Exhibition buildings have been tested by them during the winter and spring. Less than a month ago there was a gale which, for forty-eight hours, advanced at the pace of sixty miles an hour. The buildings, however, withstood it very well. Strange to say the tendency of the glass was to fall outwards, and some of it even was blown back into the building. In order to protect visitors from injury by falling glass Mr. BURNHAM, the director of works, has decided to make use of 1,045,000 square feet, or about 24 acres, of wire netting, to be placed under the roofs of the four main buildings. The netting to be used will have a 2-inch mesh and consist of No. 18 wire. Tests were made with sheets of glass dropped 12 feet upon the netting without perceptible effect upon the screen. It is proposed, however, to place the netting only one foot below the glass. The amount of netting in the principal buildings will be:—Manufactures and Liberal Arts, 600,000 square feet; Machinery Hall, 170,000 square feet; Agriculture, 145,000 square feet; Fine Arts building, 130,000 square feet. The arrangement is novel in exhibition buildings, but it is often employed in American railway stations.

THE relation of builders to sub-contractors was exemplified in a case which was heard in the Crewe County Court on Wednesday. The plaintiff, a builder, superintended alterations in a house belonging to Lord TOLLEMACHE. The defendants obtained the contract for painting, &c., which amounted to about 700*l.* As the money for payment passed through plaintiff's hands he claimed 34*l.* 17*s.* 6*d.*, being commission at the rate of 5 per cent. One of his witnesses, a local builder, said that when contracts were sub-let it was the custom of the trade for the first contractor to receive 5 per cent. on the amount of the contracts sub-let. Judge HUGHES said that if it was the custom of the trade he should not allow it to be the custom of the court. He gave judgment for the defendants, but said that they appeared to have made a promise of some commission to the plaintiff. The case is curious, for the plaintiff appeared in two characters, as honorary superintendent (he said the occupier of the house did not pay him) and as first contractor. It is not wise to go through dual performances in an English court, and the plaintiff might have gained his case if he simply appeared as a contractor, although the question would be sure to arise why he did not deduct his commission in the payments.

THE annual meeting of the members of the Liverpool Engineering Society was held on Wednesday. Mr. H. PERCY BOULNOIS presided, in the absence of the retiring president, Mr. ROBERT E. JOHNSTON. According to the annual report there were 240 members of all classes, of whom three were honorary, four life members, 215 ordinary members, eight associates and ten students. The Chairman, in moving the adoption of the report, referred in high terms to the work done by the hon. secretary. The following officers were appointed for the ensuing session:—Mr. H. P. BOULNOIS, president; Professor HELE-SHAW and Mr. A. J.

MAGINNIS, vice-presidents; Messrs. M. C. BANNISTER, J. A. BRODIE, S. B. COTTRELL, G. FARREN, T. L. MILLER, W. E. MILLS, J. MORGAN and E. S. WILCOX, members of the council; Mr. R. C. F. ANNETT, hon. secretary; Mr. COARD S. PAIN, hon. treasurer; and Mr. W. S. BOULT, hon. librarian.

THE sixth annual meeting of the Sheffield Society of Architects and Surveyors was held at the School of Art on Tuesday evening. The retiring President presided, and there were present also Mr. T. J. FLOCKTON, Mr. J. B. MITCHELL-WITHERS, Mr. E. M. GIBBS, Mr. C. HADFIELD, Mr. W. F. HEMSOLL, and many of the members. Notes of apology for non-attendance were received from Messrs. F. FOWLER and J. E. BENTON. The Society appeared from the annual reports to be in a flourishing condition. The classes for the study of design, architectural history and sketching, inaugurated in the early part of the session, under the management of Mr. GIBBS and Mr. J. R. WIGFULL, were attended by several young architects, and supplied a much-needed educational want. A beginning had been made towards the formation of an architectural library. A ballot took place for the election of officers for the ensuing session, with the following results:—President, Mr. E. M. GIBBS; vice-president and treasurer, Mr. J. B. MITCHELL-WITHERS; hon. secretary, Mr. C. HADFIELD; council, Messrs. T. J. FLOCKTON, F. FOWLER, C. J. INNOCENT, J. SMITH and W. C. FENTON. A vote of thanks was awarded to the retiring president, Mr. INNOCENT, for his two years' services. Afterwards Mr. HADFIELD read a paper on "The Church of St. Peter at Rome and the Vatican Basilica," which he had visited during the recent Papal jubilee in February last.

WE are informed by Mr. BURNHAM that among the congresses to be held in Chicago during the exhibition season, under the auspices of the World's Congress Auxiliary, is an International Congress of Architects. The meetings will commence on July 31 in the Permanent Memorial Art Palace, on the Lake Park front of Chicago, near the centre of the city. The object of the Congress is to bring together the architects of all countries for friendly intercourse, comparison of methods and results, and the promotion of their mutual interests in the profession. What is particularly desired from the architects of each country is a clear and graphic presentation of the progress, achievements and special lines of development in architecture. To this end the following subjects have been selected:—Working-men's houses; modern apartment houses; ancient apartment houses; laundries in houses, health effect; kitchens in houses, health effect; modern stables, large and small; responsibility of architects in constructional matters; responsibility of architects as to plans; responsibility of architects in decorative matters; sculpture and architecture; painting and architecture; the client's right to service, as to drawings; ownership of same, specifications and details, as to supervision, &c.; mechanical engineering in architecture, and the architect's responsibility therefor; modern steel construction; fire-proofing of building to date. Mr. ROBERT CRAIK McLEAN, 19 Tribune Building, Chicago, is the secretary for the Congress.

IN the recent numbers of *L'Art* there are etchings after some of REYNOLDS's paintings of children. With such subjects the French artists have to enter into competition with English engravers, whose plates are now very costly. It is most creditable to *L'Art* that so much success has been gained. We must remember that English children differ in type from the French, and it was no easy matter to secure fidelity to subjects which do not correspond with the little ladies that are to be seen in the parks of Paris. The new presentments of REYNOLDS's children should be secured at once by collectors. There are other English subjects among the plates, and *L'Art* is the only French periodical in which the merits of English artists are recognised in a generous manner. This sense of justice is one of its characteristics, for whatever work is described, ancient or modern, in the pages of *L'Art*, it is sure to receive fair-play.

THE IMPERIAL INSTITUTE.*

IT is not easy with a language like the English to find rhymes that will describe an important building with precision. When, therefore, Mr. LEWIS MORRIS wrote in his ode for the ceremony on Wednesday—

Lo! the airy domes and towers arise
Clear on the vernal skies.

Not of our colder Northern Art sedate,
But lighter, blending East and West in one,
A flower of Fancy quickened by the sun,
Yet keeping still, to guard our Regal state,
The Lions at the gate.

Here, in the stately chambers everywhere,
And corridors with veined marbles, fine, &c.,

we must take the will for the deed, and excuse him if his description is not technically correct. The Imperial Institute can be made a great agent for the welfare of Great Britain and its dependencies. There is no doubt the building is worthy of so important a purpose. That was the general opinion on Wednesday, and there were many who were surprised that the architect's labours were not rewarded by some dignity.

* The illustration is from a special photograph by Messrs. Bedford Lemere & Co.

THE JOHANNESBURG EXCHANGE.

WE publish the design of this building which, with the House of Deputies at Bloemfontein, Orange Free State, designed by the same architect, and already published in *The Architect*, represent the two most important buildings erected in South Africa since the Cape-town Houses of Parliament were constructed many years ago. The greater portion of the building was constructed before the railway reached Johannesburg, and therefore the whole of the materials, except the bricks, had to be carried over three hundred miles of bad roads in waggons. The fittings and furnishings were supplied by well-known English firms, and the work was carried out by Mr. A. L. LAWLEY, of Johannesburg, under the superintendence of the late firm, Messrs. LENNOX-CANNING & GOAD, architects, Johannesburg, now represented by Mr. F. LENNOX-CANNING, F.S.A., architect, Johannesburg, and 5 Copthall Buildings, E.C.

THE IMPERIAL INSTITUTE.

THE formal opening of the Imperial Institute has drawn new attention to the project which the building may be said to embody. It is therefore interesting to recall the history of the Institute, which was ably narrated on Wednesday by the *Times* as follows:—

No one ought to feel more gratification to-day than His Royal Highness the Prince of Wales, to whose unrelaxing efforts the Imperial Institute owes its existence. We have referred to the Institute as the outcome of the exhibition which was opened seven years ago. But, indeed, such an Institute was a cherished project of the Prince of Wales years before the Colonial and Indian Exhibition was thought of; we can, in fact, trace the idea further back still, and one wonders why it has taken so long to assume concrete shape. As long ago as 1851 a scheme for a permanent Colonial Museum was mooted, and a detailed plan drawn out for its establishment on the grounds occupied by the present Institute. Since then the idea has been prominently brought forward on several occasions, specially so in connection with the removal of the India Museum to South Kensington in 1876, when the late Dr. Forbes Watson advocated the establishment of a joint museum for India and the Colonies. Two years earlier the idea of combining within the same building a Colonial and an Indian museum was seriously discussed in high quarters. When in 1874 the proposal to erect an Indian Museum in Charles Street was under discussion, there was sitting at the Colonial Office a Museum Committee for the purpose of providing for the permanent representation in London of the resources of the colonies. These schemes unfortunately came to nothing; the time was evidently not ripe. But to show how firm a hold the project had taken of the minds of our best public men we may quote a passage from a paper dated December 27, 1875, addressed by Sir Erskine Perry to Lord Salisbury. After saying that this was a scheme which had long been germinating in the minds of some of our deepest thinkers in India and the Colonies, he proceeds:—

An institution, in the Metropolis which, with a museum and associated library, shall in the first instance present to the existing genera-

tion an epitome of the various productions, the arts, the clothing, the habits, dwellings and archaic history of the hundreds of millions who owe allegiance to the British Crown would not only be of the greatest assistance to the manufacturing centres of these islands and a mine of information to the scholars of Europe, who are slowly working out the early origin of our civilisation, but, housed in a building of fit architectural proportions, would be a monument to all time of the greatness of England in the latter half of the nineteenth century.

These words were quoted in an article on "The Proposed Imperial Institution" in the *Times* of October 1886, when it was pointed out that "they almost exactly embody the conception of a monumental Imperial Institution to commemorate the greatness of our beloved Queen's reign which is entertained by all who have thought over the subject disinterestedly, in the light of Her Majesty's honour and the best welfare of the Empire, colonies and mother country combined."

The words, indeed, must strike every one as embodying in brief the plan on which the Imperial Institute has been organised. In the same article in which they were quoted a detailed description was given of what, it was suggested, ought to be the lines on which the proposed institution should be worked out, lines which, it is gratifying to state, have been in the main followed.

It is in 1878 that we first find the name of the Prince of Wales associated with the project of a Colonial Museum. This was in connection with the Paris Exhibition of that year. In an address from the Colonial Commission to the Prince as President of that Commission the belief was expressed that—

The erection of a permanent Colonial Museum in London, where the products and manufactures of Her Majesty's most distant possessions might at all times be on view, would diffuse throughout the mother country a better knowledge of the nature and importance of the resources of the several dependencies of the Empire, would facilitate commercial relations, and aid the researches of men of science. It would assist in marking the progress achieved from time to time, and afford valuable information to intending emigrants.

The Prince of Wales gave his hearty support to the proposal, and obtained space at South Kensington for the storage of such goods as the colonial representatives might desire to retain as a nucleus for a permanent collection. Unfortunately, the necessary co-operation and support from the colonial governments were not forthcoming, and the collections stored at South Kensington went to ruin, and were finally mostly carted away as rubbish.

Most naturally, then, the idea of a great Imperial Institute was revived in connection with the Colonial and Indian Exhibition of seven years ago. In the circular letter of the Prince of Wales to the Agents-General, dated November 24, 1884, the possibility of a permanent Colonial Museum growing out of the exhibition was very plainly intimated. As a matter of fact, the exhibition was scarcely opened when the idea of converting the collection into a permanent Colonial and Indian Museum took definite and practical shape. In an article in the *Times* of May 31, 1886, the first announcement of the proposed institution was made. In that article we said:—

"Certainly such an opportunity of founding such an institution may never occur again. No doubt the present collection would require a little weeding and some additions, but that could be easily done. In working out the scheme let the representatives keep steadily in view the good of their several colonies; that is the one object for which a permanent museum should be established. Other points might be decided in the light of the various classes at home for whose enlightenment a Colonial Museum would be of service. From the colonial point of view capitalists and possible colonists, merchants and mechanics should come to look upon it as the great centre for colonial information. At the same time, it should be so attractive as to become a favourite public resort. The institution ought, of course, to be a living one; there ought to be a constant influx of fresh specimens and constant renewal of old ones."

We cannot help quoting the concluding paragraph of that article:—

As to the term museum, it is not a happy one for an institution which will illustrate the living present more than the past, though certainly the past should no more be unrepresented than it is at the exhibition. Unfortunately, the Colonial Institute has already appropriated a more suitable term. How would "Imperial Institute" do? For surely the institution in view will contain much that will illustrate the intimate connection between all parts of the Empire, including the mother country herself.

And "Imperial Institute" it is, as we suggested.

But that was a false start. There were the usual inevitable jealousies and bickerings, and it was only after various compromises had been considered and abandoned that a scheme was finally resolved upon worthy of the object in view and adequate as a memorial of Her Majesty's Jubilee, with which in the end the scheme became intimately associated. Up till the end of October, 1886, under all the phases which the project had assumed, the leading idea of the executive of the exhibition had been to continue the exhibition on the then existing lines;

indeed, at one time it was proposed that the institution should be designated the Permanent Colonial Exhibition. That the representatives of the Colonies were favourable in the abstract to a permanent institution that would display their conditions and resources in all their aspects there can be little doubt, but there was a strong feeling of distrust towards the scheme as proposed by the executive. The continuation of the exhibition, in which the tea-gardens and illuminations, the eating, drinking and philandering had become the prominent features, was certainly not looked upon with favour by those whose support it was indispensable to secure. When the movement became associated with Her Majesty's Jubilee, it took a new departure and was raised to a higher platform. The Prince of Wales took into his counsel the men best fitted to advise him in so important a matter, and the institution which the Queen opened on Wednesday gradually took shape. All idea of reopening the Colonial Exhibition in 1887 was abandoned. It was resolved to make efforts to obtain the large funds necessary to construct a building which, while it would be a worthy monument of Her Majesty's Jubilee, would at the same time be an outward and visible symbol of the great Empire over which she reigns, and illustrate the products, the manufactures, the commerce, the scenery, the people of each section of that Empire. A broad plan for the internal organisation of the Institute was laid down by the influential and representative organising committee in December 1886, and in June 1887, Mr. Colclutt's plans for the building were adopted from among several others. The foundation-stone was laid by Her Majesty on July 4, 1887, and since then the work of building has proceeded steadily. The front of the building is nearly completed, but a good deal still remains to be done in other parts. Up to the present considerably over 300,000*l.* has been spent on the structure. As far as outward appearance goes, it is a fitting monument of Her Majesty's Jubilee and a worthy addition to the great public buildings of the Metropolis.

On May 12, 1888, a charter of incorporation was granted to the Institute by Her Majesty. Three years later a form of constitution was prepared, and a governing body appointed, which may be said fairly to represent all the important interests involved, and all the great corporations of the Empire. Of course, the work of an institution of such magnitude could not be carried on without ample funds. It was estimated at the start that it would take at least half a million to place it in a state of what we may call initial efficiency. Up to date something like 420,000*l.* has been received by way of donations from the various parts of the Empire, the bulk of it in the way of private donations, only a small proportion being official contributions. Part of this sum has been appropriated as a permanent endowment fund, which stands at about 142,000*l.* The number of Fellows of the Institute is rapidly approaching 8,000, and will probably in a comparatively short time amount to 10,000; the annual subscription of these, combined with the income from the endowment fund, will yield a substantial income, but not sufficient to carry on with efficiency the many operations which form part of the functions of the Institute. There is reason to believe that the colonies will add to the contributions already given. They will, of course, maintain their own courts in the Institute, and there can be little doubt that, if convinced that the Institute will help in promoting the development of their resources and the increase of their commerce, they will see it to be to their interest to maintain it in a state of efficiency. So far the development of the original idea has been thoroughly successful. The Prince of Wales has taken an active personal interest throughout every stage of the progress of the Institute; and he has been most ably and efficiently seconded by the secretary, Sir Frederick Abel, and the assistant-secretary, Sir J. R. Somers Vine. There has so far been every reason to have confidence in the conduct of the Institute, and we are bound to believe that nothing will occur to shake that confidence.

The objects of the Institute are very clearly and succinctly set forth in the charter:—

1. The formation and exhibition of collections representing the important raw materials and manufactured products of the Empire and of other countries, so maintained as to illustrate the development of agricultural, commercial, and industrial progress in the Empire, and the comparative advances made in other countries.
2. The establishment or promotion of commercial museums, sample-rooms and intelligence offices in London and other parts of the Empire.
3. The collection and dissemination of such information relating to trades and industries, to emigration, and to the other purposes of the charter as may be of use to the subjects of the Empire.
4. The advancement of trades and handicrafts by exhibitions of special branches of industry and commerce, and of the work of artisans and of apprentices.
5. The promotion of technical and commercial education, and of the industrial arts and sciences.
6. The furtherance of systematic colonisation.
7. The promotion of conferences and lectures in connection with the general work of the Institute, and the facilitating of commercial

and friendly intercourse among the inhabitants of the different parts of the British Empire.

8. The doing anything incidental or conducive to carrying into effect all or any of the foregoing purposes.

These are manifold functions, and it would be obviously unfair to expect that at this early stage every one of them should be in running order. During all the years that the building has been in progress of erection; however, the executive have not been idle. Not only have they been organising their various departments, but they have actually been doing active work, one evidence of which is the handsome handbook which was published during the past year. But it is only now that the building is open that we can expect a serious start to be made.

GOVERNMENT BUILDINGS AT VICTORIA, B.C.

THE decision in the above competition is in favour of the design submitted by Mr. F. M. Rattenbury, of Vancouver. The five sets of plans submitted in the final competition were analysed by the experts under the several heads of "Entrances," "Staircases and Passages," "Design and Composition," "Light, Air, Lavatories," "Construction," "Detail," "Heating, Ventilation and Drainage"—the principal heads on which the award was based. As the result of this analysis, the designs were placed in the following order of merit:—

1. "For our Queen and Province" (F. M. Rattenbury, Vancouver, B.C.).
2. "Spes Labor Levis" (T. C. Sorby, Victoria, B.C.).
3. "Caractacus" (F. M. Garden, Chicago).
4. "A Red Seal" (J. M. Corner, Boston, and W. P. Skilling, Seattle).
5. "Dieu et Mon Droit" (J. Francis Brown, Toronto).

The following particulars regarding Mr. Rattenbury's design, which is in the Classic style, are given in the *Victoria Colonist*:—

The buildings are arranged in three groups—the centre or principal building comprising six departments so arranged that, whilst each of the three wings will be a perfect and complete building that can be erected independently of the others, they will when completed form a monumental and impressive pile. The grand entrance in the centre of the façade leads into a central octagon hall, terminating in a nobly proportioned dome. From this octagon hall on the ground floor the Minister of Education's department is approached on the left; the Treasury is on the right, and the Lands and Works department in front. On the first floor the same arrangement is repeated with the Provincial Secretary's department on the left, the Attorney-General's department on the right, and the legislative hall and offices in the centre. Thus from this one hall is every department immediately approached, all confusion or perplexity being entirely obviated. And while each department thus forms part of one central scheme, it has nevertheless its own independent entrance, staircases, strong rooms and lavatories, rendering it a perfectly contained and independent block.

The grand entrance is a handsome enriched portal, approached by a grand flight of steps. Through this the visitor enters the dome, which ultimately may be enriched by sculpture, mosaics and decoration. A flood of light is shed down from the cupola at the apex. On special occasions the entrance can be reserved solely for the legislative hall, the departments on either side having their own special entrance as before described. The legislative hall is situated in the centre of the block and has a corridor round it with a belt of rooms for the use of the ministers and members, committee-rooms, library, &c.

The hall itself is a spacious and beautiful room. On three sides an arcade is carried round, with galleries for the public, ladies and reporters, obtained over the corridor.

On the third floor the Lieutenant-Governor has a suite of rooms in front, facing James Bay and approached by the elevators next the principal entrance.

An unique and ingenious method of protecting the building from fire is adopted. At the approach to the three departments on each floor from the central hall a system of iron doors or bulkheads is arranged, so that in case a fire might occur it can be isolated to one wing and controlled, without there being any possibility of its spreading. The heating and ventilation are also carefully considered. This is the principal block. Two others, perfectly fireproof, one on each side, are arranged for the Land Registry office, on the right, and the Government printing office, on the left. The two detached buildings at either side stand somewhat in advance of the principal building, looking on the plan somewhat like the three sides of a square. These are connected to the main structure by a colonnade of columns, forming a covered approach from one to the other.

The winner of this competition is a young man under thirty years of age, who arrived in British Columbia from England about a year ago.

THE TUDORS AND ART.

THE sudden transition which painting experienced in England, from the state of high esteem in which the favour of Henry VIII. maintained it, to the neglect into which it sunk immediately after his death, in consequence of the proscriptions issued against the greater part of its works, is the most important circumstance in the history of English art.

That monarch, finding the period in which he reigned distinguished by the fame of the great Italian and German painters, had endeavoured to attract the most celebrated masters of their art into his kingdom. He invited to his court Raphael, Titian and Holbein, the last of whom became a resident in London. Although unable to prevail with the former two, he still persisted in his favour towards them, and procured from Raphael the picture of St. George, afterwards possessed by the King of Spain, and from Titian two pictures afterwards in the Stafford Gallery. Holbein was lodged in his palace and employed in various historical works. It appears also that, like the other sovereigns of his time, Henry was desirous of calling into action the utilities of the art, for we find in Walpole's "Anecdotes of Holbein" that "he invented patterns for goldsmiths' work for enamellers and chasers of plate, arts much countenanced by Henry VIII.," and that he made also "designs for weapons, hilts, ornaments, scabbards, sheaths, sword-belts, buttons and hooks, girdles, hatbands, and clasps for shoes, knives, forks, salt-cellar and vases, all for the king."

When ecclesiastical reform was instituted Henry appears in all his acts to endeavour carefully to separate the legitimate respect for statues and painting in churches from unauthorised regard towards them. His sentiments with regard to the admission and use of statues and pictures in churches are fully expressed in his first injunctions, as head of the Church of England, in 1538, and in a publication called "A Necessary Doctrine and Erudition for any Christen Man, set furthe by the Kynge's Majestie of England" (printed in May, 1543).

The following passages there occur in the exposition of the Second Commandment, wherein a full direction is given for setting up images in churches, "to be as booke for unlearned people to put them in remembrance of those sayntes, of whom they may learne examples of fayth, humilitie, charitie, patience, temperaunce, and of all other theyr virtues and gyftes of God. As for an example, the image of our Saviour hangeth on the crosse in the roode, or is paynted on clothes, walles, or wyndowes, as an open booke, to the intent that besydes the examples of virtues, which we may learn of Chryste, we may be also many wayes provoked to remember his paynefull and cruell passion, and also to consyder ourselves, when we beholde the same image, and to condemne, and abhorre our synne, which was the cause of his so cruell death." His letter to Cranmer, in 1542, is to the same effect.

In conformity with those sentiments, Henry continued to the last to protect the works of art in the churches from the indiscriminate zeal of the reformers; but the rein having once been given to iconoclastic fury, it could not lightly be checked, and in the beginning of the reign of Edward VI. a letter of the Protector and Lords of Council addressed to the same Archbishop of Canterbury runs thus:—"Considering therefore that almost in no place of this realm is any sure quietness, but where all images be clean taken away and pulled down already, &c., we have thought good to signifie unto you his Highness's pleasure, with the advice and consent of us the Lord Protector and the rest of the Councell, that immediately on the sight hereof you shall not only give order that all the images remaining in any church or chapel within your diocese be removed and taken away, but also by your letters signifie unto the rest of the bishops within your province, this, his Highness's pleasure for the like order, to be given to them," &c.

Nor was even this strict charge thought sufficient. It was followed by a statute in 1549, in which is the following article:—"And be it further enacted, by the authority aforesaid, that if any person or persons, of what estate, degree or condition soever he, she or they be, body politick or corporate, that now have or hereafter shall have in his, her or their custody, any books or writings of the sorts aforesaid, or any images of stone, timber, alabaster or earth, graven, carved or painted, which heretofore have been taken out of any church or chapel, or yet stand in any church or chapel, and do not, before the last day of June next ensuing, deface and destroy, or cause to be defaced and destroyed, the same images and every of them, and deliver or cause to be delivered, all and every the same books, &c., to the mayor, &c., &c., shall, after the said last day of June (being thereof lawfully convict) forfeit and lose to the King our Sovereign Lord, for the first offence xxs., and for the second offence shall forfeit and lose (being thereof lawfully convict) ivl., and for the third offence shall suffer imprisonment at the King's will."

To these acts of prohibition succeeded in 1559 an "Injunction given by the Queene's Majestie, as well to the clergie as to the laitie of this realme, in the fyrst yeare of our Sovereigne

Lady Queene Elizabeth," two articles of which run thus:—"Also that they shall take away, utterly extyncte and destroy all shrynes, coverynge of shrynes, all tables, candlestykes, tryndalles and rolles of waxe, pictures, payntinges and all other monuments of fayned miracles and superstycion, so that there remaine no memorie of the same, in walles, glasses, wyndowes or elsewhere within their churches and houses," &c. "Item, that no persons kepe in their houses any abused images, table, pictures, payntinges and other monuments of fayned miracles, pilgrimages, ydolatrie or superstycion."

In the convocation held by the archbishops in the thirteenth of the same reign, among other canons, this for taking down and defacing pictures and images was one. The canon (eighteenth) runs:—"That the churchwardens shall see the church kept clean; the Holy Bible to be in the churches; and the holy homilies, lately set forth against rebellion; and all rood-lofts, wooden crosses, pictures of false and feigned miracles and all other relicks of superstition destroyed and demolished; the walls of the churches to be new-whited, and sentences of Holy Scripture to be written upon them in great letters."

The exercise of this power in the hands of churchwardens, during a time of religious controversies may be easily imagined. The charge of new-whiting the churches was a sweeping commission that left no compromise. The homily against idolatry had also particular reference to the pictures on the walls of churches.

Nor was the practice of destruction confined to the above-mentioned depositaries of religious judgment. "In the Queen's time," says the Attorney-General, in a State trial, 8 Car. I., "many went abroad, of their own heads, to break down crosses, images and pictures of all sorts." This violence proceeded to such excess that a proclamation became at length necessary, stating that:—"Whereas many violent persons have of late, of their own authority, gone about to deface the walls and glass windows of churches; and in their violence have pulled down tombs and monuments of noblemen and gentlemen deceased, to their dishonour and to the breach of our peace; therefore a strict commandment is given, that all men forbear to break the pictures set upon tombs or graves, and not to break the pictures or portraictures of the noblemen or others in churches, church-walls, windows, &c., nor any images whatsoever, without the advice of the ordinary, or the advice of the Queen's Majesty, or her Council," &c. Given 44 Eliz.

The Queen's proclamation, although it might suppress particular violences and regulate the actions of men of rational opinions, did not abate the popular prejudices against the unfortunate arts of design. "I undertake," says a witness at the same trial, "there are some spirits now, that, if they had been alive in Solomon's time, would have gone nigh to have done violence to the cherubims. God knows what would have become of them."—(State Trials. Proceedings against Henry Sherfield, Esq., for breaking a painted church window. 8 Car. I., 1632.) Under such persecution the arts were not able to maintain their ground. Their professors sunk into poverty. One amateur named Hillier expressed himself about their condition in this way. "If a man be so induced by nature, and live in time of trouble, and under a government wherein arts be not esteemed, and himself but of small means, woe be unto him, as unto an untimely birth, for of mine own knowledge it hath made men poorer, as amongst many others, the most rare English drawer of story works." It is probable that few adventurers were found to supply their places, and the field was therefore left open to the occasional speculations of foreign artists.

PAISLEY TOWN HALL.

AT the meeting of the Paisley Town Council it was reported by the Town Hall Committee that Mr. Lynn, architect, Belfast, to whom the designs for the painting and decorating of the Town Hall had been submitted, had given the first three places to the designs submitted by Messrs. A. & J. Scott, Glasgow, and Messrs. Cowan & Stewart and David Murray & Son, Paisley. In his letter Mr. Lynn stated that the designs of Messrs. Scott and of Messrs. Cowan & Stewart were of equal merit. The offers for the work were subsequently submitted to Mr. Farquhar Matheson, measurer, who reported on them as follows:—A. & J. Scott, painting 658l. 9s. 11d., and decoration 100l.—total, 758l. 9s. 11d.; Cowan & Stewart, painting 732l. 6s. 9d., and decoration 130l.—total, 862l. 6s. 9d.; David Murray & Son, painting 862l. 13s. 9d., and decoration, 150l.—total, 1,012l. 13s. 9d. Other designs:—Painting offers, David Bett, 466l. 7s. 2d.; James Paul & Sons, 536l. 0s. 1d.; John Orr & Sons, 721l. 10s. 6d.; C. Carlton & Sons, 758l. 6s. 9d.; McCulloch & Co., 894l. 7s. 6d. The above probable costs include for ceilings and walls only of large hall, loggia, principal entrance, corridors and principal stairs, and were calculated on the assumption that four coats of paint would be sufficient for the whole work. Messrs. Scott's design was adopted.

THE CONTINUITY OF CONVENTIONAL PATTERNS.*

MODERN criticism has its own prejudices and its own narrowness. It is very loud in its announcement of the evolution theory, but it is very illogical in supposing that there has been no evolution in the field of ornament. I shall try to show in this paper that it is in blunt contradiction with the researches of its own anthropologists when it asserts that geometric ornament is the initial starting-point of primitive man. According to the *Critic*, "Given the tools and an instinct for decoration, geometrical ornament will spontaneously follow," but when we examine history we find that the earliest ornaments of primitive man were very life-like pictures of the mammoth and other animals, the drawings on bone and horn of the Palæolithic epoch. For the moment let us remember where we obtained our own theory of conventional art, how long we have had it and how very apt we are to transplant the habits of thought created by it to the art of other days, without authority and without reason.

It is the limitation in number, the simplicity and the widespread modern use of these conventional traditional patterns that has caused the belief that some of them are spontaneously generated whenever and wherever an ornament is wanted. That they are found both in ancient and modern art at remote distances in various quarters of the world, and at points which appear to us to have been inaccessible to one another, is undoubtedly true. That they are universal is not true; that they are common or elementary or indigenous forms in primitive art is not true. That they have ever been spontaneously generated in Europe is positively untrue. I shall show what amount of historic continuity can be proven for them, and when this has been done I think that the advocates of the spontaneous generation theory will admit that its case is very much in suspense, not by any means a matter of course, and certainly not a case which will justify its advocate in patronising an opponent.

I do not think it has been suggested that the Ionic capital, the "honeysuckle" or the egg-and-dart moulding have ever been spontaneously generated, but it is the prevailing view that the meander, the various forms of spiral ornament, the guilloche and the rosette are "reinvented every time an untaught person tries to invent ornament," and that "they are found in the ornament of every savage tribe that has attained a little skill." But all seven motives named, and some few other motives, belong to one ornamental system, and have never been used in Europe, apart from historic connections with their original system, since the Greeks, and have never been used in Europe since prehistoric ages, without distinct dependence on the Greeks. As found with the Greeks they can all be traced back to Egyptian sources, except the guilloche, which is only a later variant of the spiral scroll.

I will not stop now to debate the origin of any of these forms, and I will waive the egg-and-dart moulding, as regards even its mention in the Egyptian category, if any one should desire me to do so, as its motive is only found in Egypt in the form of a flat lotus border inverted. But still let us stop a moment to consider this point of historic continuity for the ornaments named, in block. The Egyptian rosette can be dated to the Fourth Dynasty, 4000 B.C. Since that time its history has been continuous. Since its first transmission to Europe it has never been reinvented in Europe, for there was never an occasion or a chance to reinvent it there. The spiral scroll is dated to the Fifth Dynasty. That, too, has had a continuous history since that time down to the nineteenth century, as far as Europe is concerned. The meander is dated at present to the Thirteenth Dynasty, about 2500 B.C., and the same point holds again for its European history after that date. The Egyptian Ionic capital is dated to the Eighteenth Dynasty, 1600 B.C. The Egyptian anthemion ("honeysuckle" original) is dated to the Twelfth Dynasty (about 3000 B.C.). In the various cases mentioned the dates are for the earliest known cases among the very rare instances of positively dated ornaments for very early times, and a considerably higher antiquity than the given date must be assumed in all cases. The lotus border originals of the egg-and-dart moulding are certainly much older than the Eighteenth Dynasty to which we can positively date them.

Some of these ornaments travelled all over Europe in the prehistoric period. None of them, however, appeared in Europe before the age of bronze, and they moved with the arts of metal partly by land, partly by Phœnician commerce, from the south and south-east to the north and north-west. From the days of the Greeks downward the history of all these forms and patterns is continuous in Europe. In the Middle Age, when Classic art was nominally or apparently abandoned, the surface patterns at least are historically continuous. The anthemion can be verified for all periods of the Middle Age. The Ionic capital survived till the twelfth century at

least. The egg-and-dart moulding can be verified for the twelfth century at Arles. The rosette was never given up. The spiral scrolls are historically continuous and the Egyptian lotus trefoil (*fleur de lys*) is a conspicuous instance of continuity.

With the Renaissance period the Greco-Roman motives were all revived, and many of them had survived without reference to this revival. It is not long between the last days of Classic art in Southern France and the first days of the Italian revival in Pisa. From the time of the Renaissance to the nineteenth century all these motives have been strictly traditional. They have been carried along by the great waves of civilisation which have moved from the Renaissance, from the Greek revival, and from the recent studies of historic art. Their continuity is a phase of the one essential fact of the history of civilisation, that man never reinvents anything that he finds ready-made to hand. They met all the natural demands for ornamental patterns. They were passed on from one decorator and artisan to another, as the matter of course things to do.

Now I urge that the history of ornament in Europe establishes a preliminary presumption that these ornaments when found elsewhere may not have been created independently or spontaneously, and outside the American continent we have not the slightest difficulty in proving a positive case.

I will now take up successively the patterns for which the claim has been especially made that they "are reinvented every time an untaught person tries to invent ornament." It may be well to mention the ethnographic collections on which I base the following statements. They are the New York Natural History Museum, the National Museum at Washington, the South Kensington Museum, the British Museum, the Pitt-Rivers Museum at Oxford, the Trocadéro in Paris, the Kircher Museum at Rome, the Ethnographic Museum of Amsterdam, the Ethnographic Museum of Berlin, and the Ethnographic Museum of Leyden. The two last-named are the finest collections in the world, and I have made a careful study of their evidence, having examined thousands on thousands of objects to reach my conclusions.

Notwithstanding the enormous number of objects from the Pacific Islands in Berlin and in London, the Leyden collections must be placed first. They are much more comprehensive and systematic as regards a balanced choice of objects for all local centres, for the Pacific Islands in general, and above all they are connected with a representative exhibit for the Malay Archipelago which is simply unique.

When these various ethnographic collections have been examined it appears that the conclusions obtained for Europe regarding the meander are substantiated. So far from being a universally employed or spontaneously generated pattern, it is distinctly traditional outside of Europe, as far as we can trace its history. It is unknown to barbaric Africa; it was not used in ancient Mesopotamia. It is foreign to Mohammedan and Arab art. Its sporadic appearance in Asia, India, Thibet, China and Japan is due to Buddhist influences. The Buddhist art is the earliest that we know in India (third century B.C.), and at its first appearance is saturated with Greek influences through the Greek states of Bactria founded by the successors of Alexander the Great and through the commerce then actively carried on with the West. These same Buddhist influences by way of farther India would explain its occasional appearance in the decoration of the Malay Archipelago, where it is by no means common. The meander is so rare in Polynesia that the Leyden collection contains only two examples, and I have not observed a single other Polynesian instance in the magnificent collections of London and Berlin.

In order of prominence among the formal linear patterns which are traditional in nineteenth-century use, we may next mention the spiral scroll. Most of our spiral scrolls have a Renaissance derivation—that is, they are survivals of fifteenth and sixteenth-century Italian copies of Greco-Roman originals, which in their turn are derived from the earlier Greek, and these again are decorative evolutions from Egyptian patterns. When our spiral scrolls are not Renaissance, they are copies dating from the Greek revival of the late eighteenth and early nineteenth century, or they are copies taken by recent decorators from the recent publications of historic decorative art. The theory of spontaneous generation, the supposed natural aptitude of anyone who has "tools and an instinct for decoration" for making spiral scrolls without reference to tradition, shipwrecks utterly when brought face to face with historic facts as far as Europe is concerned. Tradition is not only the rule, but it is a rule without exceptions.

Theorists and reviewers (who are generally more than twenty years old) can sit down at a desk and design a spiral scroll on the writing-pad which will carry their article to the press. They will then announce on the same writing-pad that any child can do the same thing, and that primitive man can do, and does do, anything that a modern civilised child can do. But somehow it happens that reviewers and children who have grown up, or are growing up, surrounded by the originals of the

* From a paper entitled "Are Conventional Patterns Spontaneously Generated?" by Mr. W. Henry Goodyear, in the *Architectural Record* (New York).

forms which they fancy themselves to be inventing, are not the people who are called upon to design decorations for the market. Decoration is a trade which presupposes, like all other trades, a special education and compels it. This education is either traditional, that of the artisan—say a stove-maker—who recasts an old pattern with or without slight modification, or it is special, the education of an architectural school or a school of decorative art, where the pupil is surrounded by historical examples whose influence comes to the same thing.

The question is not whether a person who braces himself up to answer Mr. Goodyear's theories could not invent something new in the way of a spiral, but the question is, whether before the time of theoretic instruction in decoration, which never existed before 1850, anybody who was an artisan decorator ever did brace himself up to do such a thing. When the question is put in this way the argument is all on my side to anyone who knows anything about the history of ornament.

As a matter of fact under normal conditions, wherever and whenever a new departure is made in ornament, that new departure will be from a natural form or a natural phenomenon. Where the pattern is abstract, schematic, or apparently purely linear, that pattern will be a traditional survival of a form which was once also a form of nature, and the modifications made in it will have been gradual and evolutionary.

I am speaking now of the spiral scroll especially, and having asserted that all our motives of this character are fundamentally Classic, and Egyptian before they were Classic, I wish to speak of the spiral scrolls of other ornamental systems, mainly to say that, like the snakes in Ireland, there are none—none, that is, that are not derived from the system under discussion.

We have seen already that the earliest Hindoo art known to us is Buddhist under Greek influences, and we must turn now to the "Moorish," or more correctly, Arab Mohammedan system, to notice that this also is of ultimately Classic derivation. Aside from Persian influences on Arab art, which again go back to the same original elements, Arab ornament was derived from Syria, Egypt and North Africa (all of which were Byzantine [Roman-Greek] provinces) in the seventh century A.D., and at the time of the Mohammedan conquest of these countries from the Byzantine Empire. The dependence of the Arabs on Byzantine culture has been well explained by Mr. Freeman in his lectures on the Saracens, and is otherwise a commonplace of the average historian. All the Arab and Mohammedan spirals (generally with lotus trefoils) are modifications and evolutions from the Byzantine Greek. If you will turn now to a map of the area of the Mohammedan religion, which means Mohammedan art and culture also, you will find it reaching in Africa from the shores of the Mediterranean to the river Gambia, to the Niger, to Lake Tanganyika, and to Zanzibar.

In Asia we find the Mohammedan colour spreading from Arabia, Asia Minor and Persia through Turkestan into Siberia as far as the river Ural, as far as Tobolsk, as far as the Irtysh and the Obi. We find the Mohammedan colour spread over India, in the peninsula of Malacca and the Malay Archipelago, Sumatra, Java, Borneo and the Celebes. Now let the reviewers who assert the spiral scroll to be one of the natural ornaments of barbaric man consider the point that it does not occur in barbaric Africa at all, excepting in cases of palpable Moorish or Arab art. I have seen it, for instance, on some very rude brass vases of Moorish design from the Niger, in Berlin. Otherwise it does not occur in the Niger or the Congo country or in other parts of barbaric Africa. The Somali and Abyssinian ornament is of course Arab.

If we turn to the Malay Archipelago, as compared with Polynesia, the case for the historic traditional continuity of the spiral scroll becomes a certainty. It is here that the ethnographical collections of Leyden come in play, the only systematic and complete collections for the Malay Archipelago in the whole world. Let us remember now that the ornamental system of India was, in the first instance, as known to us, Buddhist, under Greek foreign influences as explained; second, Arab Mohammedan. The spiral scroll ornament of modern India is a mixture and survival of the two. (The more formal Classic style of old Buddhist ornament has disappeared in India.) This is the ornamental system of the Malay Archipelago. One of the most astounding monuments of Buddhist architecture is the ruin of the temple of Boro Boeder on the island of Java. The present ornamental system of Malaysia is mainly the Mohammedan Arab. The Malay alphabet, the Malay ornament, the Malay religion and the Malay culture are all derived from India. Now let the theorist, as to the innate ornamental habits of primitive man, consider that the spiral scroll is absolutely foreign to the ornamental systems of Polynesia, of which there are several. The limit of the spiral scroll eastward in the collections of Leyden is the Admiralty Islands, bordering on New Guinea, which is part of Malaysia.

In the Admiralty Islands it is sporadic. In Leyden there are only two instances. In the Berlin collections the sporadic cases of the spiral are found in other islands also adjacent to New Guinea, south-east of the Admiralty Islands. Considering that the whole of Polynesia is conceded to have experienced

influences from the Malay Archipelago, we should not be startled at the sporadic appearance of spiral scroll ornaments farther east than the Admiralty Islands, but since I have reviewed the Polynesian collections of New York, Washington, London, Amsterdam, Berlin, Oxford, Paris, Rome and Leyden, and the publication of Partington for Polynesian ornament, I am willing to rest my case with the simple statement that the spiral scroll is foreign as such to all the ornamental systems of Polynesia, and that the system of the Malay Archipelago is the Mohammedan Arab, which is derived from Byzantine Greek.

There only remains the case of New Guinea and New Zealand. Not only does New Guinea border directly on the Malay Islands, but it is geographically part of Malaysia. The princes of the island of Tidore have actually been the potentates of the northern coast of New Guinea. The New Guinea ornamental system shows degraded and barbaric forms of the Mohammedan spiral scrolls of Malaysia. From these once more are derived the spiral scroll ornaments of New Zealand.

The Maoris are supposed emigrants from Tahiti, but the ornamental system of New Zealand has no relations with this supposed earlier home of the Maoris. It will show the possibilities and surprises of intercourse in this part of the world to say that a Japanese bell was found in the possession of the Maoris which had been in New Zealand before the time of the first European settlers. My informant is Dr. Codrington, the great authority on Polynesian and Melanesian languages.

Now let us turn to the evidence of the Berlin ethnographical collections, which are simply marvellous in the mass and comprehensiveness of their material for the areas below named. Once more, and this time through Buddhist transmission, we can trace the spiral scroll from the Amoor Valley, where the ornamental system is as familiar to us as that of the Malay Archipelago, through the Yakoots of Siberia to the Aleutian Islands and Alaska.

I have re-examined last summer in the museums of Berlin and Leyden and in the Pitt-Rivers Collection of Oxford the question of the spontaneous generation of the rosette, with the following conclusions:—The area of this ornament is far more limited than the area of those just considered. In modern use it is historic and traditional. In ancient European use it was limited to Mediterranean countries and their influences, originating in Egypt and transmitted to Mesopotamia, Phoenicia, Greece and Italy. Its use was more and more limited in the later Greek and Roman art, and consequently in the Byzantine, and I am not acquainted with it in Arab use to any marked extent. It was extremely common in ancient Buddhist art, but appears to be rather more limited in modern Hindoo survivals. It is unknown to barbaric Africa and unknown to Polynesia, unknown to New Zealand and New Guinea, mainly unknown to Malaysia. Its rare appearance in ancient American art must be classed with problems suggested by the normal lotus in the same art, in stone-carvings and in gold, and I think can only be explained by direct transmission from the ancient Mediterranean world. There is no pattern of which it can be asserted with so little reason or show of reason, that it is common and natural to all barbaric and primitive peoples; for it does not appear to be common or native with any. The rosette is an obvious combination for modern Kindergarten scholars who are taught to make elementary geometric patterns and to use petals of flowers and floral forms as suggestions for geometric combination—but I do not care to have my case damaged by an appeal to the Kindergartens. I prefer to appeal to history and to the ethnographical collections of the world.

I would recommend above all to inquiring minds on this general subject of the continuity of the historic patterns, a study of the ornamental systems of the Pacific, as showing what barbaric man really does do and how many different things he does, when he is left to his own ornamental instincts without the extraneous influence of a superior civilisation. A natural appearance of phenomenon of some kind or other appears to be the invariable starting-point. As the pattern itself then becomes a tradition and the point of departure for a new copy, this is gradually simplified until all semblance of the original is lost. The human figure or some portion of it was undoubtedly, in many cases, the initial form. In the Pitt-Rivers Museum, at Oxford, there is a series of paddles showing the gradual transformation of a human figure carved upon them, into a crescent supported by a bar. There is also the case of a fish head used to decorate the junction of the paddle blade with its handle, which finally degenerates into the shape of a capital letter W. There are multitudes of these designs which cannot be explained for want of the connecting links or of the originating form, but I believe it is the conviction of experts in this department that a purely arbitrary or ideally schematic form was rarely or never the first element of the pattern. The introduction of different colours in weaving or basket-work to produce diaper patterns would perhaps be the only exception to this rule. That the figures of men, fish, animals and birds, which originated patterns, were fetiches and totems—that is to say, religious emblems or rather talismans—may be always taken for granted.

BUILDING IN AUSTRALIA.

IT would appear from an article in the trustworthy Year Book of Australia that at present building is not a profitable business in the colony. The following explanation of the causes is offered:—

What has been accomplished in Australia during the past year in the way of architectural achievements and developments is illustrated under its chief aspect—that of the practical—by the appended list of principal buildings. Yet withal, that part of architecture, *i.e.* its realisation in actual bricks and mortar, &c., has suffered lately a great falling-off throughout the colonies. Few buildings of any importance now remain to be finished, and outside of Government contracts, which are also considerably lessening, and which will continue to do so with the reductions in staffs that are so general, there will, it is feared by many, be really nothing new started in the way of art building for some time to come. Of course, lots of proposed designs have been “on the boards,” but these are still *in statu quo* as drawings merely, and are now “hung up,” awaiting better times before they can be taken in hand and carried out. This lack of work will then be most conspicuous in the coming year; therefore it may perhaps be as well to refer to the cause of such a state of things, and suggest possible improvement. The main reasons for this slackness of enterprise, architecturally, are unfortunately the same as those through which every other department of life suffers, *viz.* the depression after the enormous expenditure in the land boom, and over (speculative) building times of 1888, *et seq.*; the conflicts of labour *versus* capital; the subsequent demoralisation and failure of financial and other institutions and prominent individuals; and the present loss of confidence of English and other investors. All this has involved want of work and employment, and augmented an already grievous deficiency in our national revenues; so that altogether the money market and all its appertinings are in a very perilous condition through the consequent paucity of funds. Thus have been necessitated schemes of retrenchment and taxation. Truly a big burden for the colonies to carry are these accumulated bad effects of ill-advised actions, and they press more heavily on the combined arts and crafts of architecture than on any and everything else. Yet, if we can profit by the lessons they teach us, may they not, after all, be but blessings in disguise? As regards the situation the excitement of the land fever time has placed us in, it is but to be expected, for the nineteenth-century tendency is proneness to exaggeration, and it is seemingly a specially sad sign of this *fin de siècle* decade. Over-hilarious hopefulness in a time of high prices is now matched by futile feelings of depression and dejection when the inevitable period of depreciation and deterioration in values sets in, and the one is as erroneous as the other was fallacious. Half a decade back fully four-fifths of the people considered that land in the various outlying suburbs was bound to run up to metropolitan prices, and that it must be got hold of at any figure. Now the vogue is to treat land as absolutely worthless, which is a decidedly absurd extreme. For while, of course, there may have been want of balance in believing we were in 1888 entering on a monetary millennium, still it is showing similar mental obliquity to discredit and decry our present position, and maintain that we are going down into a bottomless pit of bankruptcy. Let us rather adopt the happier mean, and be trustful that things will quietly brighten, our narrowed lane have an ampler turning, and our sense of tightness and straits give way and open out into paths of pleasantness and peace. Such a way of looking at affairs is really our heritage in these latter days, and we ought to live up to our privileges. Really we moderns are responsible for sanguine views in such matters, for the ancients, the Mediævalists, and the men of the Renaissance period even, had no such store of faith to guide them. In those olden times the factor of variableness in prices was so conclusively patent that fluctuations of land values became recognised as a thing of course—that is, if they ever bothered to think about them at all. Now the *raison d'être* of a “boom,” *ipso facto*, predicates such and such a transaction being considered a good investment, and argues, therefore, that a rise in prices is only a question of time. Well, and where can we look with such certainty for such a result as in these colonies if the natural resources are only given proper scope and outlet? What other countries for their years would be so self-reliant under such (to them) unlooked-for trouble and trials as the Australian colonies have been? Think of how New South Wales, Queensland, South Australia and Victoria have lost lately in the various ways before referred to, as well as in other unforeseen directions—Brisbane losing fully a million in one year through fire and flood, and other portions of our dominion also suffering severely; and yet they all keep up a good front before the world. Surely that speaks volumes for the inherent power of endurance that the colonies possess, and which has undoubtedly kept them from feeling and showing the strain and struggle in a much greater degree—as they well might—than they have done. Why, at this juncture, after all said and done, the country—the real backbone of our nation—

teems with plenty; the fields are heavy with the harvest, and the vineyards laden with fruit; wheat, wool and butter, corn and wine and oil, in fact, all kinds of produce, point to profitable returns, and the prospects are most promising in our staple and stable industries. Then, we have not the drawbacks of our mother country and the continental nations—the chances of war, pestilence or poverty, with all their glaring and ghastly concomitant evils, to enfeather our Austral homes. That we have attained our admittedly high place and position in the short space of a century is true; but it has been consistent progress in the most progressive of centuries, and it is not in the nature of things that we can possibly retrograde. So it needs but the proper, hopeful, insistent spirit being instilled into our minds again to inspire us with the firm belief that we are approaching a time when what we have already attained will be as nothing. In the dawn of that period of prosperity the Australian empire will then look upon this ugly epoch of its history as only noticeable in the grand era that succeeded as being one of the natural links in the chained sequence of events that bound them the more coherently together. Another of the causes that have influenced, and still influence, stagnation in architectural matters is the want of appreciation—we could almost say distrust—of architects generally, shown by the major proportion of the public who should make use of their services.

AMERICAN COMPETITIONS.

IN a communication to the *Engineering Magazine* Mr. Barr Ferree writes:—There seems to be no diminution in those relics of uncivilised times—architectural competitions. Every year some important mercantile building is decided by this cumbrous, expensive and unnecessary method, which is as sensible as if a sick man were to send for a half-dozen doctors and promise to engage the one that would effect the speediest cure. How long this state of things is to continue it is idle to predict, but, being an unavoidable evil, it is clearly right to make it as little an evil as possible and to eliminate from it every possible suspicion of unfairness. Architectural competitions, unfortunately, are looked upon in so many quarters as perfectly natural and proper things that the methods of conducting them are very well known, very well understood, and, so far as the architect is concerned, very well systematised. A well-drawn competition programme is a thoughtful document, embodying a multitude of details and requiring a wide acquaintance not only with the practice of architecture, but with the entire history of architectural methods. It is a document that cannot be drawn by every architectural practitioner, and, as might be expected in this era of specialism, we are gradually producing a small school of competition-programme makers, who, if this system is to be continued, must before long exercise an influence on current architecture quite out of proportion to their merits. It is hard for the most conscientious programme-maker not to infuse his personality into it, to indicate his own personal inclinations as to style and treatment, to tell the architect, so far as he dares, how to treat the problem, it is only his business to indicate in the most summary fashion. Much of this is unavoidable, but the influence of this hidden and powerful force in current architecture is not to be despised. In the limited competitions which are now the fashion, the most careful scrutiny is exercised as to the architects who shall be invited to compete for it. Their merits and demerits, their advantages and failings, their good work and bad, are all passed in review, and the very best selected. Yet who examines the programme-maker, who questions his authority or his competency, studies his prejudices or makes allowances for his idiosyncrasies? He needs looking after as sharply as the architect. He may be, if he chooses, a most dangerous man.

The professional programme-maker is a natural product of the competition system. Under our present architectural fashions he is more likely to be a teacher of architecture in an architectural school than a practising architect. For some reasons such a person possesses many advantages for the work. He is not distracted by the labours of actual practice; he has time to give to study, for which the busy man of affairs can devote no moments. Years of exercise in criticisms of youthful drawings have trained his mind in critical methods, even though the material on which it has thriven has not been of the healthiest and most invigorating kind. All of these are distinct advantages, and coupled with the fact that he has probably had much experience in these things—else how could he be a professional programme-maker?—make him a very proper person for this sort of work. But he has his disadvantages, as have most people and much architecture. The teaching of architecture, as the teaching of any subject, tends to keep the teacher's mind in a single rut. He views things from the academic standpoint, and in this country knows no architecture save that taught in the Rue Bonaparte. In other words, the architectural teachers of this country have so positively made up their minds that the system of the *Ecole des Beaux-Arts* is

the only one to be employed in instructing young architects that nothing else is considered necessary for their training. Instructors in construction must, perforce, keep pace with the gigantic constructive strides American architecture is now making; but the teacher of the art of architecture, as the more ornamental side is often wrongly called, and who is most likely to be the professional programme-maker, knows no architecture save that of Paris and its world-famous school. A person so trained is not in the least fitted to draw up a programme for a competition for a business building, for example. What have orders and columns and friezes to do with a business building? One has only to look at those examples in which they occur to find an answer. The professorial professional programme-producer—to give him a stated title—is out of touch with much modern work. Living in a single style, he sees solutions in it only, and his programme is drawn up accordingly. An architect, finding hints of the Classic strongly stated in the programme, necessarily imagines that he must follow them. And thus the professorial professional programme-producer helps along his own school by forcing the use of his style, whether it be really suited to the problem in hand or not. The retarding influence he can exert on the progress of American architecture may not always be recognised, but it is nevertheless a fact. The creators of competitions should examine his merits, as well as those of the architects they invite, before putting his work out upon a long-suffering, though perhaps indifferent, world.

If the antecedents of the professional programme-maker need to be looked into in every well-ordered competition, the antecedents of the jury should be not less carefully studied. The deciding of competitions, as well as the drawing up of their programmes, is rapidly falling into the hands of the professors of architecture. Architects in active practice are either taking part in the competition, or do not wish to give the time and thought necessary to the judging of a series of architectural designs. Besides, the mental agony incurred in looking at atrocious designs is likely to interfere with the work of an artistic architect for some weeks to come. And so, the architects not being available, the jury plums fall to the professors. And people more unsuited to such work it would be hard to find. Professors, like other folk, have their prejudices and failings, their inclinations and preferences. They like one style, abominate another and look with indifference upon a third. The style they like is doubtless the only one they know, since even a professor of architecture cannot know everything; certainly it is the one they are apt to judge by, because it is the best. Here comes a new element for the architect. He not only has a programme drawn up by a biased hand, but he knows that, if he wishes to gain a certain competition, he must follow the inclinations and prejudices of his jury. An architectural jury, unlike one in a court of law, does not judge by facts but by prejudices. If an architect knows its members to be classicists, he knows as well as he knows anything that, if he sends in anything but a classical design, he will have his trouble for his pains. He might, if he has a strongly-marked individuality, work out a thoroughly practical design in some other style, but he wants that building, and bends his mind to an uncongenial task, and then wonders why he did not get the prize. Thus the architectural professor retains his grip upon current architecture, though its methods and necessities may be quite foreign to his style of thought and art. Both the professional jurymen and the professorial professional programme-producer are legitimate products of the competition system; yet both are fundamentally opposed to the true progress of architecture. To a very large extent they are a neglected element in current architecture, but they are getting in their innings with the wisdom of the proverbial early bird. A true appreciation of their real nature must help to destroy much of the present false confidence in the unquestioned merits of competitions, as it will likewise help to make clear their inherent unfairness. Meanwhile the programme-producer and the jurymen should be carefully selected in every case. They cannot, if architecture is to live, be permitted to become a class.

Abominable as architectural competitions necessarily are, some good words may be spoken for the Bill passed by the late Congress permitting limited competitions for public buildings. If there has been one phase of American architecture more atrocious than another, it surely has been its official side. Americans do not naturally do foolish things, but they clearly exceeded all previous records when they evolved an architectural system whereby a single office, and nominally a single architect, should be responsible for the huge number of Government buildings yearly erected in this country—a number now estimated at about 300. And in order to make things as bad as possible—as if this in itself were not sufficiently preposterous—all of this was to be done by an architect holding office for not more than four years, and often for less, and, as likely as not, as incompetent to undertake work on this gigantic scale as he was to earn the meagre salary of the post by private practice. It is no wonder, that the architects of this country

have been protesting for years against the horrors of this situation, and it is no credit to the intelligence of our national legislators that years have been necessary to bring about a reform. The new law contains many imperfections, and is not at all what it should be, but it is a move in the right direction. The secretary of the treasury is now authorised to institute a competition limited to five architects for any public building at his discretion. This is the substance of the law. It is not mandatory, it need not be applied in every instance, and only the successful architect is entitled to compensation for his plans, which are to be executed under the supervision of the supervising architect of the treasury. Insufficient as the law is, it must work many important and long-needed reforms. Whether under it our official architecture will take a fresh lease of life and thrive and flourish in a way long unknown to it may be doubted. But then this art could not by any possibility be worse than it is, and there is every reason to believe that the present entering wedge will prepare the way for further efforts and more successful results in the near future. For several years the chief business of the meetings of the American Institute of Architects has been the discussion of such a law as this, and the taking of measures to secure its enactment. The present legislation is largely due to the activity of that body, but its occupation is not yet gone. There is much to be done yet for the furthering of American official architecture, and of American architecture in general, before the Institute can regard its chief mission as finished.

OXFORD, ROUEN AND NUREMBERG.

A LECTURE was delivered recently to the members of the Department of Architecture, Brooklyn Institute, by Mr. Albert E. Parfitt, architect, upon "The Three Types of Architecture as expressed by Oxford, Rouen and Nuremberg." The illustrations were thrown on a great screen from original and very fine lantern-slides.

He began by remarking that someone has said that nations write their histories in three ways—in the book of their deeds, in the book of their words and in the book of their arts, and that to read one of these books alone is to remain for ever ignorant of a great part of that nation's history, and of these three ways the most trustworthy is the last, the book of their arts. No writings express the religious fervour of the Middle Ages so well as the noble towering cathedral buildings and their sublime imaginations chiselled in stone. The huge monastic buildings scattered over Europe tell the story to-day with peculiar force of the growth of these institutions and of their life and habits.

The idea in selecting three cities, Oxford, Rouen and Nuremberg, to express three types of architecture is an attempt to describe certain characteristics of local art rather than national, for it cannot be said that Rouen expresses the art of France, but rather some of the best phases of the art of France of the Middle Ages. Neither can Nuremberg be taken to express the art of Germany, but rather of one of her imperial cities, but Fate has so preserved this city that there is probably no town in Germany whose external appearance is still so Mediæval, and gives an idea of its old-time wealth and influence.

The city of Oxford well illustrates the gradual evolution of English architecture. One can walk through her churches and college buildings and see excellent and well-preserved examples of Norman, Early English, Decorated, Perpendicular, Elizabethan, Jacobean, English Renaissance and the revived Classic and modern revived Gothic style of the present day. There is no special "lay-out" to the city, the irregularity of which in some measure is the cause of its most picturesque effects. The groves and avenues of trees, the quiet college gardens, the absence of large factories and tall chimneys, all combine to make Oxford the fairest city in England. Quadrangles are a special feature in Oxford; nearly all the colleges are planned on this system, and certainly for beauty they are unsurpassed, affording, as Hawthorne says, "a sweet, quiet, sacred and stately seclusion." Magdalen College, from its singular beauty, might be rightly called the queen of Oxford's colleges—beautifully situated by the river Cherwell, its massive tower rising up as if to guard the noble bridge, which forms a continuation of the High Street. We do not know who really did design this fine structure—indeed, we know but little of the designers of the Middle Ages; but during its erection Wolsey, the great cardinal of the time of Henry VIII., was bursar of the college, so that his name has always been associated with it.

The effect of the interior of Christ Church Cathedral is surprisingly beautiful; over the stern Norman columns in the choir a gorgeous pendentive roof of stone hangs, reminding us of the Henry VII. Chapel at Westminster. Contemporary work in Europe at this period (which was about the date of the discovery of America) shows Classic influences and Gothic art abandoned, but here in England comes the climax, and it seems that the resources of Gothic art could go no further.

The Reformation came, and the era of large ecclesiastical buildings came to a end.

With our practical nineteenth century we have too much forgotten the art life. We speak of art to-day as if it were some advanced technical accomplishment rather than as it should be, the bringing out of the best behaviour of things. How often do we see buildings quarrelling at each other, rooms which make us feel at swords' points, colour in wall-paper and carpets which depress us. Up to the last century everything seemed to have gone along very well, but in the last 100 years, the 100 years which have made the greatest progress in the science and arts, it has yet to account for the woeful supply of food for the art life. Oxford is not scientific; Oxford is artistic. Who can measure the influence of her charm upon the cream of England's youth who study within her walls?

Then the scene changes to Rouen, the old capital of Normandy, and although the distance from Oxford, as the crow flies, is scarcely 200 miles, a totally different city in almost every respect. Probably no town of France has so many relics of Mediæval architecture.

The relative importance of the cathedral to the city is generally very marked. The old-time builders insisted that the Lord's house should dominate everything, and be the most conspicuous structure when viewed from any point; it was placed in the heart of the city, and usually its portals were entered from the market-place. The mind instantly recalls how the dome of St. Paul's is still the crowning point of London's pictures; and so it is, too, with Cologne, St. Peter's at Rome, the Duomo of Florence, not to say anything of the smaller cathedral cities—Amiens, Salisbury and Chartres.

The south-west tower of the cathedral, called the Tour de Beurre, derives its name from having been erected with the money paid for indulgences to eat butter during Lent. Most people think this tower more beautiful than the Tour St. Romain, but from this opinion the speaker begged to differ. Both towers are about 250 feet high, or 50 feet less in height than the spire on Holy Trinity.

The front of St. Ouen Church faces the Rue de la République, a broad avenue like our Flatbush Avenue and about the same grade, and like it, too, crowned by a fountain. The fountain St. Marie was designed conjointly by sculptor Falguière and architect Depertthes, and has a fine sky-line. The group at the top represents Rouen seated in an antique ship; the water which gracefully falls over the basins has been aptly termed architectural water, for in this kind of monumental art the French stand unrivalled, and sculpture seems as natural a production to them as patent invention is of the American.

Rouen during the latter half of the fifteenth century and the beginning of the sixteenth century (the period of the discovery of America) was the scene of great building operations. Under such patrons as the Cardinals de Amboise, Rouen for nearly a hundred years was the metropolis of art and taste in France, and was one of the first towns where the splendours of the Renaissance burst forth. To-day it yields to no provincial city of France in majestic and venerable aspect and in the triumph of the ecclesiastical and civil architecture of the Middle Ages.

From Rouen to Nuremberg as the crow flies is about 450 miles, but there is just as marked a change in the architecture as between Oxford and Rouen. Nuremberg was formerly among the richest and most influential of the free imperial cities of Europe, and is one of the few cities that has retained its Mediæval aspect substantially unimpaired. It is still surrounded with its ancient feudal walls and moat, though of late several breaches have had to be made to meet the exigencies of modern traffic. Of the reputed 365 towers which formerly strengthened the walls, nearly 100 remain, and a few of the interesting gateways have also been preserved.

The general effect of Nuremberg is certainly quaintly picturesque, and the desire of her present builders to carry out the lofty-peaked gables and oriel windows and red-tiled roofs of the older houses is certainly praiseworthy, for as one rambles through the crooked streets one is not shocked as in Rouen by some incongruous front of the Parisian style standing beside some old monarch of the olden days, but the new houses, built to the requirements of nineteenth-century wants, are yet within the spirit and traditional style of the city—a true architectural evolution.

The ancient fortifications consist of a rampart encircling the city, provided at intervals with towers of various forms and a moat now dry, over 100 feet wide and 35 feet deep. This moat is now planted with trees, while a broad road encircles it, making a continuous park-like walk around the whole city.

If from our saunterings around Oxford, Rouen and Nuremberg we have felt the majesty of true art, said Mr. Parfitt in conclusion, if we have felt that these cities are dear to us, if we have felt that they have lessons to teach us to-day in our rapidly growing America, and if we have felt the need of more poetry in the material make-up of the trivial round of our everyday life, in our street scenes, in our business haunts, in our churches and our homes, that is all which I have wished to accomplish.

GLASGOW ARCHITECTURAL ASSOCIATION.

A PAPER was read at the last monthly meeting of the Glasgow Association by Mr. John A. Macara, M.A., B.Sc., on "Monuments and Memorials of the Dead." Dealing with the subject in an historical manner, the lecturer described in detail and by means of lantern slides a great variety of tombs and monuments of the different periods of architecture. Egypt, which may be regarded as the birthplace of art, was first noticed, and an interesting account given of the Pyramids and the other commemorative monuments of that country. Passing on, he alluded to the monumental remains of Assyria, Greece and Etruria. Roman remains of this kind are also very numerous, and exhibit many points of interest to the architectural student. Touching briefly on the monumental art of Mediæval and Renaissance times many interesting examples were shown. A short discussion followed, and at the close a vote of thanks was awarded the lecturer.

GENERAL.

The Designs for the Sedgwick Memorial Museum prepared by Mr. T. G. Jackson, A.R.A., have been approved, subject to any modifications in detail that may hereafter be found desirable.

The Foundation-stone of the Bishopsgate Library and Institute will be laid to-morrow by the Rev. William Rodgers. The building will cost over 50,000*l*.

The Winchester College Quingentenary is to be commemorated by raising a fund which will be applied, first, to the restoration of the founder's chantry in cathedral; and, secondly, to establishing a group of memorial buildings for the preservation of Wykehamical antiquities and the encouragement of art, archæology, natural history and other sciences. The buildings are likely to cost 10,000*l*.

A Portrait by Albert Dürer, which belonged to the Rev. H. R. Cholmondeley, was purchased on Saturday by the Director of the Berlin Gallery.

The First Commissioner of Works has announced that a portion of the site at Millbank will be reserved for the purpose of erecting examination-rooms for the London University, in connection with the provision of examination-rooms for the Civil Service Commissioners, but he was unable to say when the buildings will be commenced.

The Council of the Irish Institute of Architects have indicated the Dublin Chamber of Commerce to seek for the extension to Ireland of the Arbitration Act of 1889.

A Statue of Fritz Reuter, the poet, by Professor Wolff, has been set up in Newbrandenburg (Mecklenburg-Strelitz). It is larger than life, and is in bronze.

Mr. William Henman, of Birmingham, has been successful in the competition for the Smallwood Hospital, Redditch, and has received instructions to carry out the work.

The Carpenters' Company have inaugurated a series of lectures at Carpenters' Hall on Wednesday evenings (commencing Wednesday, May 10), on carpentry and joinery. The list of lecturers includes Professor Banister Fletcher, Mr. Thomas Blashill, Mr. Keith D. Young, and Professor J. Roger Smith. The lectures are given with a view to future examinations, and candidates' tickets and particulars may be obtained at Carpenters' Hall.

The "Standard" says:—A most interesting and important antiquarian discovery has been made at Delphi. In the course of the excavations now proceeding under the direction of the French Archæological School, the workers came upon a building having the form of a small Doric temple, which is believed to be the Thesaurus of the Athenians mentioned by Pausanias. Five metopes have also been found, on which the figures of Athene, Hercules and the Centaurs, and many warriors and animals can be distinguished; as well as some one hundred and fifty inscriptions.

Mrs. Parr, of Killiechonan, Mull, has offered to give 2,000*l*. for the building of a cottage hospital at Oban.

The Duke of Sutherland has offered to the Longton Town Council a site in Stone Road for the erection of new municipal buildings.

Sir Charles Tennant presided at the seventy-eighth anniversary dinner of the Artists' General Benevolent Institution in the Whitehall Rooms, Hotel Métropole. The annual report showed that last year over 5,000*l*. were distributed. Subscriptions were announced to the amount of 2,204*l*., including 100 guineas from the chairman and 85*l*. which he had collected.

The Mansion-house of Kirkdale, in Kirkcudbrightshire, has been totally destroyed by fire. It was an imposing structure of white granite, the seat of Lieutenant-Colonel Hannay, and tenanted by Mr. Charlesworth.

The Architect.

THE WEEK.

THE late JOHN M'LACHLAN, who died on Saturday last, was not among the most successful of the Edinburgh architects, but no man could be more esteemed. He was essentially "a good fellow," and when he came to a conference in London several years ago he made friends of all who came in contact with him. Among his qualities was a sense of humour, and it followed that he never excited self-derision by appearing to be greater than nature and fortune had made him. It was characteristic of his wisdom that he avoided competitions. He did not believe he could bewitch committees with noble designs, and left contests of that kind to men who were more ambitious. Mr. M'LACHLAN was fortunate in securing the work of the National Bank of Scotland, and although the branches he built could never be pretentious—for in the North banking is a more simple affair than in England—they are well adapted for business. His general practice was extensive enough to satisfy him, and clients must be exacting who were not gratified with the efforts of so honest a man. It is certain that he never gained a commission by undervaluing the competence of one of his brother-architects or by puffing himself. He was honourable in all his ways, but without affectation of that austerity which is common in the professions of Scotland. Mr. M'LACHLAN was one of the pupils of DAVID COUSIN, who was city architect in Edinburgh, and for over twenty years he practised there and secured the respect of all who transacted business with him.

A MAJORITY of the Sheffield Town Council have rejected the proposal of the architect (although approved by the Improvement Committee), that the walls of the staircase and principal corridor in the new town hall should be lined with marble at an outlay of 2,335*l.* There is no doubt that marble is more pleasant to look on than ordinary stone, but an important item of that kind should have been included in the original plans. It was considered that if the marble was allowed other extras would also be submitted. It was originally determined that the building was to cost 80,000*l.*, and under the circumstances that sum should be adhered to. No doubt it seems illiberal to deprive some of the aldermen and councillors of the satisfaction of seeing marble when they visit the town hall. But in many other places members of corporations have to submit to a similar deprivation without any diminution of their zeal in the service of the public. In cases like the Sheffield Town Hall, where designs are obtained by competition, it is the duty of the authorities to be rigorous in not allowing the prescribed sum to be exceeded. The laxity of committees who allow themselves to be persuaded about the advantage of having one improvement after another introduced in the course of the building operations has burthened many towns with an excess of taxation, for it is astonishing how much beautifying the simplest building can stand. It is also most unfair to those competitors who are exact in respecting the conditions. The decision of the Sheffield Town Council is therefore of service in insuring fair play in future competitions, and we trust it will not be set aside out of a weakness to dwell for a time in marble halls.

BUILDERS, like other classes of producers, are compelled to engage in affairs from which speculation is not absent, and if it were universally tabooed there would be an end to industrial enterprise. There is consequently no reason why the term "speculative builder" should so commonly be applied in reproach. A few days ago, in the Hanley County Court, the judge made use of the term to describe a man who would be repudiated as a representative of the builder's trade. An application was made for the grant of an order of discharge in favour of a bankrupt who called himself a builder. The judge said the bankrupt had been

carrying on a business which some people thought a dishonest one, and one that ought to be put down by the strong arm of the law, viz. that of a speculative builder. Such men as the bankrupt undertook contracts at unremunerative prices, and, getting their materials on credit, practically made the contracts at the expense of their creditors. The bankrupt had proved himself quite unfit to be a master, and should be content to be a servant. A man who conducted his business in such a disreputable and extravagant manner as the bankrupt had done deserved no sympathy. In 1878 the debtor started in business with about 50*l.* capital. Three years afterwards he went into liquidation, and a dividend of 5*d.* in the pound was obtained from his assets. Last December he made an assignment of his property, and some of the creditors had received 2*s.* in the pound. It was conclusively proved that, while knowing he was insolvent, he contracted debts. Such a case is, unfortunately, too common, but there is really no speculative element in it. When a man knowingly takes a contract at a price that cannot pay, and obtains materials which he never intends to pay for, the transaction is not a speculation, for there can be only one result, which is easily foreseen. By treating such transactions as speculative, the hands of justice are tied. The bankrupt's discharge was suspended for two years, and he was told that on another occasion it would be suspended altogether, but he and men like him merit chastisement of another sort, from which they are exempted because they are designated speculative builders.

In spite of the rival attractions at the Imperial Institute the Westminster Town Hall was densely, if not uncomfortably, crowded on Wednesday, when the annual soirée of the Architectural Association was enjoyed. The success of last year's dramatic experiment (for it would be unjust to describe so sterling a piece as a burlesque) inspired expectations in the minds of many who admire originality in stage literature, and they assembled in battalions rather than in single files, but with becoming reverence. This year the drama was entitled "Mythology run Mad, or the Chumps de Mars," and as before, it was from the practised pens of Messrs. THEO MOORE and ERNEST RÜNTZ. It is needless to say that the authors were inspired by the exalted educational spirit which has gained not only a name but a local habitation for the Architectural Association. The principal scenes were supposed to take place on the Acropolis, which is as sacred a hill for the Association as for the Athenians. Among the *dramatis personæ* were ZEUS, PHEIDIAS, MERCURY, CUPID and VENUS, names that are associated with the buildings of England as of Greece. Consistency is found to be an obstruction to freedom in all classes of compositions, and the poets wisely refused to be confined within chronological or other limits. They introduced among the representatives of the older mythology we have named Sir CHRISTOPHER WREN, the great patron of ghosts; and the untitled but hardly less famous surveyor of the Waxchandlers and other harbingers of light, JOSEPH GWILT. Their eyes also rolled in a fine frenzy as they glanced from heaven to earth, and such is the creative power of genius that natives of the county Dublin and Chicago became rivals of the Olympians. We hope, however, that members of the Association will not lose their interest in the Protectress of the Parthenon because they were affected to tears by that kindly representative of Green Erin, Mrs. MORIARTY, who, it appears, could also claim near relationship with the goddess of the thousand temples. All delight must have an element of sadness, and we suppose there were few of those happy people who were privileged to be present who did not regret that the royal lovers, the Indian princes and the Prime Minister were fated to be elsewhere, and were unable to witness a display of the histrionic art in which past and present, east and west, music and painting, dancing and singing, age and youth were combined to give homage to architecture and the Architectural Association, and immortality to the authors. Next week, when some of the fascination of the festival has evaporated, we hope to be competent to analyse the poem, which has qualities that compel us to wish that the laureateship could become a partnership transaction.

EARLY CHRISTIAN MOSAICS.

THE value of mosaics as a sort of connection between ancient and modern art has been admitted. When the race of great artists became extinct, the process of forming mosaic pictures appeared to be adapted to suit the aptitudes of inferior men. It was suitable also for the preservation of ideas in ages of tumult. Statues, paintings, works in the precious metals, ivories, miniatures, manuscripts, attracted the notice of invaders, however barbarian, and if not vendable, their destruction at least was an entertainment. But mosaics were safe as long as the buildings containing them were allowed to stand. It is remarkable that the Christians should be eager from an early period to utilise the art, not merely for pavements, but for the adornment of vertical and curved surfaces. In the Catacombs it was difficult to obtain satisfactory grounds, and the lighting might be called "a darkness visible," that was not adapted to display gradations of tesserae. But the enduring qualities of the pictures were so figurative that even in the Catacombs mosaics were to be seen. It could be said of the early artists, as of the men who raised the marvels of Gothic architecture, that "they dreamt not of a perishable home who thus could build." Amidst defects that occasionally make us think of the experiments of untaught children, we can perceive evidence of aims which there were no hands to adequately realise. The figures, with all their defects, have often fascinating power, as if they were phantoms of another world, and we may doubt whether the defects are the result of inability so much as of mysticism.

The peculiarities of mosaic work also seem to be in keeping with other forms of Christian art. In it, as in metalwork, illumination and carving of ornamentation, opportunity was given for placid labour in which thoughts could be occupied with exalted but unworldly subjects. A large mosaic afforded employment for many monks or religious laymen, who could say without exaggeration, "Laborare est orare." There is an absence of excitement about the figures which suggests that designers and operatives were generally in a contemplative mood. For these and other reasons mosaics must always have interest for the student of the history of art.

But there are aspects of the work which have not received sufficient consideration. The materials employed, their derivation, the manner of using them or the technique of mosaic-working, should have interest for artists, chemists, manufacturers and students of history. There is, however, so much obscurity about the art that few have had the courage to carry their investigations far enough to reach the early period. Much importance must therefore belong to the essay on the mosaics of the first Christian centuries which M. EUGÈNE MÜNTZ lately read before the National Society of French Antiquaries. It is one of those efforts which can only be expected from archæologists whose knowledge is as wide as their enthusiasm, and to whom the past is as vivid as the life around them. Brief as is the essay, it contains enough to inspire investigation, and it shows, too, how the clergy, overseers of restoration and even workmen can often add to our knowledge of the technique of the mosaicists.

It is a common desire to obtain the most summary expression of the qualities of things, and much appeared to be gained when it was declared that the difference between Classic and Christian mosaics was that one was made up of tesserae of marble, and the other of enamel, paste or some preparation of glass. There is no doubt the Romans made much use of marble in their mosaics, especially in pavements, but they were not indifferent to the utility of tesserae of glass. What was the Golden House of NERO except a building that had walls lined with mosaics, consisting of tesserae in which a leaf or film of metal was covered with a glazed but transparent coating? In the Pompeian houses fragments have remained unfused of enamels which are arranged in a variety of designs. The Naples Museum has a variety of examples of the kind, and amongst them are columns of stone which were covered with enamels. Tesserae of blue enamel have been found in the ruins of ADRIAN'S Villa at Tivoli, and cubes of various colours in the grounds of the Villa Borghese, in the Baths of Caracalla, on the Palatine, at Ostia, as well as in

towns of Roman Gaul, in Cologne, and elsewhere. In many cases the enamels were confounded with marble, and an acceptance of their existence would diminish the effect of the phrase "stony carpet," which is a favourite with writers on ancient Rome and compilers of guide-books. But the study of PLINY ought long ago to have taught scholars that enamels were in use. When, for instance, in describing the theatre of SCAURUS, he employs the term "e vitro" in reference to the columns of the intermediate stage, there is little doubt, as M. MÜNTZ points out, that PLINY was treating of columns which were encrusted with mosaics. The use of glass or enamel for incrustations was known long before Rome had palaces. Like so many other processes, it was employed by the Egyptians, and, for all we know to the contrary, they may have derived their knowledge of it from some other race.

We may suppose, therefore, that the early Christian artists were not the discoverers of the advantage to be obtained by using tesserae of enamel, that is to say, of glass coloured by the aid of metallic oxides. But there is no doubt they employed enamels so generally as to give some warrant to the conclusion that there was a relation, it may be only of a symbolic kind, between prepared glass and the new doctrines. Blues, for instance, were indispensable for the representation of the garments of certain saints, and as minerals of the colour such as lapis lazuli were extremely costly, it was necessary to produce the colour by the vitrification of substances. That there was no objection to the use of colours which nature provided is evident from the white and grey parts of some mosaics which consist of tesserae of marble. M. MÜNTZ says that the white parts of the vestments, and it may be, the ornaments in the most interesting mosaics of St. Vitale, at Ravenna, are of marble.

In the Church of the Nativity, at Bethlehem, the brilliant parts of thuribles and candlesticks were rendered effective by pieces of mother o' pearl. That material was also employed in the Coptic churches of Egypt, at Ravenna, Parenzo and elsewhere. A close investigation of ancient works might reveal the more frequent use of colours that were not manufactured. On the other hand, TEXIER was unable to find any natural stone in the mosaics of St. George, Salonica, which date from the sixth century. According to him, the blue tesserae are composed of cobalt and blue oxide of copper; one red was derived from ochre or oxide of iron; another red enamel much employed for flesh was similar to the purpurine, that consists of silica, potash and protoxide of copper. The violets seen in vestments were prepared from manganese. How the intense black was made remains unknown to colour-makers. Oxide of copper were also in use for green enamel. Yellow was obtained from antimony and white from oxide of tin.

Where were the chemical operations conducted that were requisite to produce the coloured enamels? Were there local laboratories or were the tesserae imported from one place? These questions cannot be solved. In spite of the extended knowledge of science in our time, it is well known that Venice and Murano supply the greater quantity of the tesserae that is used in other parts of the world. In France a most patriotic attempt is now being made to enable mosaicists to be independent of Italy; but in spite of all that has been accomplished it is still as unavoidable as ever that the orders for tesserae of particular colours must be sent to Murano. Frenchmen have also to submit to the inconvenience of seeing very crude colours for the sake of the support of a new industry. Can we suppose that ten or fifteen hundred years ago it was more easy to manufacture enamels than it now happens in Paris? May we not rather conclude that the refugees who found security among the islands of the lagoons, in the first years of the fifth century, discovered the value of the materials about them, that the making of enamels was one of the earliest of the industries, and that supplies of tesserae were among the earliest exports? M. MÜNTZ shows that in 1359 one DONNINO, a Florentine, contracted with the authorities of the cathedral of Orvieto to supply the enamels that were needed for the restoration of the mosaics of the façade, and to obtain them from Venice. It is not improbable that in the arrangements the precedents of the earlier Mediæval period were repeated, as well as those of a more distant age. Simple as they may appear, tesserae need more than chemistry and machinery can always supply if they are to

constitute a mosaic picture that will be gratifying to the eye, and among people who were more susceptible to harshness or disagreement of colours than we can be in modern cities, it was necessary to be careful in the selection of materials. Ravenna would be likely to rebel if such a mosaic as was lately completed in the Louvre had been introduced in the humblest of the churches.

There is another question no less interesting but hardly more soluble that is started by M. MÜNTZ. In our days it is necessary to have elaborate cartoons for the use of the mosaicists. Owing to the modern organisation of industry the mosaicist's art is becoming more and more mechanical, or rather machine-like, and he or she is not allowed to exercise any thought. Were the earlier mosaicists treated more rationally? It is supposed that in the days of the BIANCHINI and ZUCCATI some members of the craft in Venice were compelled by the authorities to depend on the painters for designs, while others were allowed to carry out their mosaics without external aid. Now the question that M. MÜNTZ proposes is whether in earlier periods the mosaicist followed a cartoon, and if so, who was the author of it? A most important contribution towards the attainment of knowledge on the subject has been furnished by M. RIOLO the elder, who is superintendent of restoration at Palermo. He has scrutinised the ancient mosaics in that city as well as in Cefalu and Monreale. From what was revealed to him by the display of the grounds, he believes that at first the subject was painted on the ground. When the painting was completed the mosaicists covered it with tesserae of corresponding colours, and in that way were bound to express not only form but colour with exactness. Sometimes there was a colour convention which was only indicative. For instance, red was employed in places where gold was to be seen and yellow marked where grey, blue and even black would appear.

It is remarkable that the tesserae used in the mosaics of the Christians are generally larger than those found in Pagan works. Where mosaics were employed in the decoration of domes or the upper part of walls it was not necessary to have the blocks as small as those seen on panels which are on a lower level. Tesserae of various sizes were sometimes employed on the same work. Those in the heads were smaller than the tesserae of garments. SALZENBERG observed this peculiarity in the mosaics of St. Sophia, and M. MÜNTZ found a similar variety in the portrait of Pope JOHN VII., which is a work of the eighth century. It is one advantage of photography that we are enabled to observe differences of that kind in the execution more accurately than is possible from drawings.

It was said by LE VIEL, in the last century, that mosaics can resist atmospheric action, and that in pavements or walls time increases instead of diminishing their *éclat*. Shopkeepers know that the finest plate-glass in windows is affected by time and the weather, and that objects exhibited in consequence become less attractive. It would be strange if glass in mosaics was exempt from the universal law of decay. On the contrary, the compound nature of the tesserae, which is a necessity of having a coloured surface, renders them liable to changes. When, for instance, we learn that the mosaics in the church of St. Paul outside the Walls in Rome were tarnished by a deposition of sea-salt, it is allowable to conclude that the enamels have attraction for deleterious substances. The fragments which are met with in the soil at Rome are found to be more or less deteriorated; sometimes the colours are completely changed. Humidity is the worst enemy of mosaics, and but for it the renowned works in Ravenna would display truer colour. It is when used for the decoration of the exteriors of buildings that mosaics are exposed to most danger. The Byzantine artists were aware of the risk, and it would seem as if they were under a sort of compulsion when they coated façades with their work. They endeavoured also to protect their mosaics by projections that would diminish the effects of variations of the atmosphere, but they were rarely successful. The records which M. MÜNTZ has transcribed concerning the mosaics of the cathedral of Orvieto in the fourteenth, fifteenth and sixteenth centuries, probably correspond with those relating to older works in the early centuries. The mosaics were executed between 1358 and 1362. In 1402 it was necessary to restore parts of them and the work was entrusted to

Pater FRANCISCUS ANTONII. In 1243, BARTOLOMEO DE PIETRO had to be called in to remedy defects. In 1485 and 1506 there were other reparations. RAPHAEL, a Florentine sculptor, was employed on the mosaics in 1552. In 1558, Master GIOVANNI ANTONIO BIANCHINI, a Venetian, undertook the restoration of the mosaics, and in 1573 Master STEPHEN operated on them. No better evidence could be given of the instability of mosaics when employed in exterior works. As the nature of the risks is now ascertained, it may not be an impossible feat to produce enamels that will resist climatic influences, and cements that will keep tesserae in their places. Some experiments made in England warrant that expectation.

M. EUGÈNE MÜNTZ has also investigated the history of mosaics in the Catacombs. He proves that much exaggeration has arisen over the extent and importance of the work in the subterranean places of worship. At the same time he describes what has survived, and from which we may infer the character of the earliest mosaics of the Christians. His essay is of value, not only as a scholarly contribution to the history of the art, but as pointing out the subjects relating to mosaics which archæologists can investigate with advantage to themselves and others.

ROYAL INSTITUTE OF BRITISH ARCHITECTS.

AN ordinary meeting of the Institute of Architects took place on Monday evening, Mr. J. Macvicar Anderson, president, in the chair.

The death of Mr. George Powell, architect, was announced. Professor G. BALDWIN BROWN, M.A., read a paper on

How to use Vitruvius.

Professor Baldwin Brown explained the object he had in view in his paper, but he thought no apologies would be needed, as the Institute scheme of examination demanded the historical study of architecture. The matter in his paper had little relation to architectural problems of the present day, as Vitruvius would not directly help the modern architect, and the study of Vitruvius belonged rather to the literary side of architecture than the practical side. There was this advantage, however, that in these days of exploration and excavation of the works of the past, and of archæological research, such explorations were carried out best by practical architects. The paper was merely meant to be a guide to those who were not far advanced in the study of Vitruvius. How to use Vitruvius was his theme, rather than the value of the work. Vitruvius was an architect and a military engineer, and the work he wrote consisted of ten volumes. In it Vitruvius gave some details of his own career, and mentioned the sources whence he derived his knowledge. What gave great interest to the work was the fact that it was the only fairly complete survival of technical literature in the past. It would be rash to assert because of its survival that it was a better work than its contemporaries. It had survived, however, and enjoyed a great reputation. The MS. of Vitruvius disposed of the contention that the work was a figment of some writer of the tenth century. There seemed little doubt that Vitruvius, as we knew it, was substantially the same as that handled by the early Cæsars. Professor Brown alluded in proof of this to quotations made by early writers, also to the parchment folio brought to light in Vienna—an epitome of the work by Faventinus, who stated he had summarised it for his own use. This document belonged to Roman times. Sidonius, bishop, made mention of the plumb-line of Vitruvius, showing his recognition as an architect in the fifth century. Vitruvius acknowledged that he drew his materials chiefly from Greek writers, and he did not describe the buildings rising in Rome in his time, buildings which continued to progress for the next three centuries. The lecturer next gave details as to the oldest copies extant, and considered that we probably owed the preservation of the work to Charles the Great. He next referred to later editions and to the first illustrated edition; to the influence of Vitruvius on the students of the Renaissance period, which could be traced in all the literature down to the later Renaissance time in Italy. The advance of criticism in the present day was opposed to the principle of authority. Everything had to submit to the ordeal of criticism, and there was a danger lest the old superstitious regard for Vitruvius should be suddenly changed into depreciation. Hardly any of the modern standard editions fulfilled all requirements. The best was that by Wilkins, and he was the only one of the commentators of Vitruvius who was an explorer and who had compared the descriptions in Vitruvius with actual remains. For three centuries philological students had laboured. It was now the turn of archæological students to bring the spade to bear on Vitruvius. The archæological spirit of the age led them to hope for a new edition of Vitruvius. Though of late years other nations might have

done more in archæology than this country, it could at any rate be said that we were abreast of all. The student who approached Vitruvius from the artistic and historical point of view would put aside certain volumes, and eliminating from the others various discussions, give his attention to the remainder, consisting of archæological and literary matter, especially to what related to materials, planning and laying out, and to the disposition of the orders in important buildings. Some such rough subdivision would be useful. The part dealing with the orders must be taken with some reserve by the modern student. The reasons for this Professor Brown gave later more at length. He went on to say that Vitruvius was born B.C. 90, and had received a good education, was known to Julius Caesar and appointed to a military command. With all his influence, his practice as an architect was but small. It was to have been expected that he would make use of his opportunities. As he did not do so, the conclusion was that he was not a man of shining parts. In a literary capacity also he showed incompetence, and his scientific studies made him a theorist rather than a practical man. This no doubt stood in his way, but whatever the cause of his failure, he was found to be a querulous quarreller, "short, old and ugly, of few means, but scorning to use the means of other architects; on his book would he rest his fame and posterity would do him due honour." This indeed came true, but the effect produced by Vitruvius on Augustus and his era was *nil*. Certain definite dates were scattered up and down the work, but it was difficult to decide whether it was the work of the great part of his life. There was no mention of the new fashions of the Augustan period, B.C. 21. The *Thermae of Agrippa* had been opened in his time, but they heard from Vitruvius only of the more humble baths, gymnasias, &c., of the Greeks. Concrete, on which Roman architecture so much depended, was scarcely recognised by Vitruvius, and that showed he was ignorant of the materials at *Puzzolana*, which had not then been tapped. After further investigation of the subject of the date of Vitruvius's career, Professor Brown remarked that the technical passages in the work were written in more simple and flowing terms than the more ambitious portions. The descriptions of plasterwork he alluded to, probably the best plasterwork ever produced. The art came from Greece, and Vitruvius described it as carried out in the Greek fashion. Chapters were to be found which took the reader through the whole series of the finest processes. After describing these at length, and saying that each of the three coats of mortar and sand were applied respectively as the last began to dry, there were three finishing coats of crushed marble and lime so carefully prepared by the Greeks to produce the final polish that left the wall gleaming white like a mirror. Later on slabs were often cut out of these walls to be inserted by persons in their rooms. The processes of the fine modelling in stucco Vitruvius did not describe, but he gave valuable descriptions of the processes of colour and fresco decoration. The canvas and primings used by painters were small matters contrasted with the careful preparation and finish of walls to be painted on, and Vitruvius had high ideas in regard of plaster work. Even the white gleam of the polished plaster he described as showing through the pigments with a good effect. Professor Brown spoke of the absence of descriptions of the great works carried out by the Romans, and among those the stupendous aqueducts carried on series of arches as seen at *Albano*, and noted that in his description of forums and theatres he had recourse to Grecian examples. The Grecian forum was, however, only an adjunct of a market-place. Too much attention had been paid to the descriptions of works personally unknown to Vitruvius, and matters within his knowledge on the contrary ignored. It was difficult to suppose that Vitruvius had ever paid a visit to Greece. Vitruvius gave Ionic as the standard order, depending probably on literary authorities. Two authorities he seemed to have relied on, *Pythius* and *Hermogenes*, architects working in the Ionic orders, the former being the architect of the *Mausoleum* and the *Temple of Athene Priene*. Having examined these descriptions by the light of our actual knowledge, Professor Brown deduced that the views of Vitruvius were practically useless in regard of temples, especially Doric temples, and also on hypæthral lighting. That the Ionic was considered by him, and not the Doric Order, showed he derived his views from others and not from personal acquaintance. He gave credit to Vitruvius in regard of his formulæ for secular buildings, which applied well in the case of porticos, showing that his writings would be of use when studying the secular buildings of Greece. Professor Brown, in concluding his paper, alluded to the capability of modern architects to build in all styles, to coquette with them all, and hinted at a wiser mode of eclecticism, and that so far the Greeks still remained the preceptors of our progressive artists where mass and proportion were aimed at.

The PRESIDENT said he saw several literary gentlemen present. These he named, and asked them to address the meeting.

A vote of thanks, proposed by Mr. Robert Kerr, seconded by Mr. George Aitchison, A.R.A., and supported by Mr. Statham, Mr. John Slater and Mr. Wm. White, F.S.A., was passed by acclamation to Professor Brown for his paper.

EDINBURGH ARCHITECTURAL ASSOCIATION.

THE annual meeting of this Association was held on the 10th inst., Mr. W. W. Robertson, president, in the chair. The reports of different officials were submitted, that of the treasurer showing that the income for the year, including a balance from the previous account, was 325*l.* 19*s.* 6*d.*, and the expenditure 250*l.* 11*s.* 3*d.*, leaving a balance of 75*l.* 8*s.* 3*d.* at the credit of the Association at the end of the year. The reduction of the credit balance, it was explained, was caused by the extra expenditure incurred during the year in removal to new premises, prizes for the work class, and the cost of illustration. The total membership of the Association, it appeared, was 279. Mr. W. W. Robertson was re-elected president. The other appointments were:—Vice-presidents, Dr. Rowand Anderson and Mr. Thomas Ross; secretary, T. Fairbairn; treasurer, Mr. J. Johnson; and librarian, Mr. Ross. Mr. Blanc, A.R.S.A., read a paper on *Corstorphine Church*. At the outset Mr. Blanc spoke of collegiate churches in general, and said they came next in importance to abbeys and succeeded them. *Corstorphine Collegiate Church*, dedicated to St. John the Baptist, was erected by Sir John Forrester in 1429, and originally comprised a chancel, nave with north and south transepts, and sacristy, western tower and porch. The nave was enlarged and the north transept extended about the beginning of the present century. Mr. Blanc next dealt with the tombs of the three members of the Forrester family, and concluded by a reference to the *sedilia*, *piscina* and other features of the church.

The President delivered an address. At the outset he dealt with the relation of the Royal Scottish Academy to architects. When after considerable delay, he said, the new charter was granted to the Academy, without the prayer of the petitioning architects for a public inquiry being granted, most of them must have felt that their action was fruitless. Looking back to-day, however, they could say it was not fruitless. Eighteen months ago there was not a single architect in the Academy, to-day there were nine. Was there any doubt, he asked, that this change was in part due to the unavailing protest of a few years ago? He did not say this by way of detracting from the grace of the Academy's recent action, but on the contrary he noticed it as a public acknowledgment of the fact that at the close of an embittered controversy, as soon as its hands were free, the Academy set itself so far as was in its power to redress some of the evils complained of. The election to the Academy of nine architects was a guarantee that in the future architecture would never again be entirely ignored by it. He pointed out, however, that the movement of the architects in the matter of the new charter was not one simply for the admission of some of their number into the sacred precincts, but that their principal object was the advancement of art. After bestowing some cordial praise on the work of the new School of Applied Art, and dealing with the work of the Association during the year, the President referred in conclusion to the controversy initiated by him upon the duty of architects in relation to ancient buildings. He commented upon the good done by the discussion in directing attention to and stimulating interest in the subject, and expressed the feeling that the debate had disclosed a great amount of agreement. They were agreed as to the paramount duty of preservation, to which he attached the greatest importance. The discussion was further useful as illustrating the revolution which had taken place in our means of restoration. Speaking especially of Dr. Rowand Anderson's views, the President said he liked his practice, as shown in the restoration of *Dunblane Cathedral*, better than his principles as expressed in some of his contributions to the debate. He was not the first man whose actions had been better than his creed. In regard to their differences he expressed the opinion that they arose not so much over general principles as over particular cases, and he declared that they were far outweighed by their agreements.

On the motion of Dr. Anderson a vote of thanks was accorded to the President.

NORTHERN ARCHITECTURAL ASSOCIATION.

THE annual meeting of the above Association was held on April 26 last at the Meeting-room, Art Gallery, Newcastle-on-Tyne, Mr. J. H. Morton, F.R.I.B.A. (of South Shields) the president, being in the chair. There was a large attendance of members. The annual report was read and confirmed. The committee, in drawing this report for the thirty-fourth session, stated that they were glad to be able to place on record the more assured position and increasing prosperity of the Association. Two prime objects had engaged the attention

of the committee:—First, the engagement of permanent rooms in which to hold the meetings of the Association, the library, &c.; second, the drawing of a curriculum of study for the younger students and a possible alliance with the Durham College. It is hoped that this may be arranged during the next session, the committee having been empowered, at a general meeting of members, to approach the college authorities with full power to negotiate the arrangements for introducing the curriculum at the college.

The engagement of permanent rooms in a central position in the city has no doubt been a great step in advance, and it is now hoped that good use will be made of the room for the reading of papers and the discussion of subjects relating to architecture and the arts generally. It is pleasant to be able to record an increasing membership. Two members, nine Associates and six students have been elected during the session, the roll now standing as follows:—Members, 31, Associates, 41, and students, 22; total, 94. It is also satisfactory to be able to announce that in connection with the Institute an examination qualifying for candidature as Associate of the Institute has been held in Newcastle, at which six candidates sat.

The committee have had several occasions during the session to bring their influence to bear on local authorities, School Boards, &c., in the matter of competitions for public buildings, with a view to obtaining the appointing of professional assessors, unimpeachable dealings, and of maintaining the status of practising architects, and in more than one instance with marked success. As usual, prizes have been offered to students out of the funds of the Association. Mr. Archibald M. Dunn very kindly acted as assessor, and awarded the first prize for the best set of sketches made during the summer to Mr. C. S. Carrington, and the first prize for measured drawings to Mr. W. Tweedy. It is proposed that one or more meetings of the winter session in the future be held in neighbouring towns, in order to extend the influence of the Association. A new bookcase has recently been placed in the meeting-room, and presents of books are asked for. Mr. H. C. Charlewood has just presented sketches from France and Italy, and Mr. W. H. Knowles in like manner has given a copy of vestiges of old Newcastle. The committee of the Institute are thanked for sending a selection of prize drawings, which were duly exhibited. The following members of the Association have passed the R.I.B.A. preliminary examination:—Messrs. E. J. Watson, E. Devereux, W. Reed and M. Martinson; and Messrs. A. Shaw and C. Rochester have passed the intermediate examination.

Excursion meetings have been held at the new Station Hotel, Newcastle; at the village of Blanchland (old church, &c.); at Messrs. Potter's cement works; and the restored church at Wallsend. On December 21 an interesting paper was read by Dr. Gibbon, on "Pompeii: Past and Present;" on January 11 Mr. J. Brown read a paper on "Varnishes," and exhibited a fine collection of gums and other matters; on February 1 Mr. Charlewood read a paper on "Stokesay Castle," and illustrated his paper by a series of carefully prepared drawings and water-colour sketches; on February 15 Mr. W. S. Hicks read a paper on "Fashion in Architecture," and on March 1, Mr. A. B. Plummer read an interesting paper on "Waltham Abbey," illustrated by a series of measured drawings.

Papers have also been read at the students' meetings, and in all cases illustrated by sketches on the blackboard, viz., on "Heraldry," by Mr. J. Twist; "Gothic Mouldings," by Mr. Errington; and "Perspective," by Mr. Boyd. The Sketching Club have held visits and return visits at Seaton Delaval, Hexham Abbey and Ponteland, and the annual social evening was held on January 24, when eighty-five members were present. The financial statement shows a balance in hand of 85/.

At the annual meeting, April 26, 1893, the resignation of the late hon. sec., Mr. F. W. Rich, was received with regret. The following gentlemen were elected to the offices for the ensuing session:—

President—J. H. Morton.

Vice-Presidents—Jos. Oswald and J. Cresswell.

Treasurer—J. T. Cackett.

Hon. Sec.—A. B. Plummer.

Committee—Messrs. H. C. Charlewood, W. S. Hicks, W. H. Knowles, F. W. Rich, J. W. Taylor, H. Badenoch and G. T. Brown.

Auditors—Messrs. W. Glover and J. Twist.

DUNDEE INSTITUTE OF ARCHITECTURE.

THE sixth ordinary meeting of the Dundee Institute of Architecture, Science and Art was held in the Upper Hall of the Y.M.C.A., Mr. William Mackison, the president, in the chair. A letter was read from Mr. Robert McGavin, of Ballumbie, acknowledging his election as an honorary member. The Chairman, referring to the competitive works submitted by various students, and which were exhibited on the walls,

said the competitions had this year been more successful than in 1892, for while then there were seven competitions and eleven competitors, this year there had been eight competitions and fifteen competitors. The names of the students who had been awarded prizes were then intimated. The Chairman submitted a suggestion for the formation of a professional union of the assistants and pupils in the district, remarking that the Association might have its own constitution and office-bearers, and the lads bring up drawings and read papers on different subjects. He was satisfied that in that way they would be able to lay the foundations of future prosperity for themselves, and become ultimately of assistance to the Institute. The matter was remitted to the Council with powers. This was all the business.

TESSERÆ.

Unknown Varieties of Greek Art.

IF, with Pausanias, we could have spent a day amid the splendid dedications and crowded statues of the Acropolis, we should have found many things to astonish us and to widen our notions of classical art, which are far too narrow and conventional, too much shaped by the Roman copyist and the Italian restorer, by the outworn views of Winckelmann and Lessing, and the conventional proprieties of the Vatican and the Capitol. The ancient Athenians were not classical in the narrow sense in which the age of the Antonines or the age of Louis XIV. was classical. They followed impulse freely, but the impulse in turn was kept in check by a clear perception of the conditions under which works of art of various sorts must be executed, and a frank acceptance of traditional types, as well as the sense of what was beautiful and the love of what was natural. One cannot but wish that some copy or record remained to us of the statue of Dütrephe, pierced by arrows, apparently an anticipation of the St. Sebastian of Christian painters, or of the bronze figure of the Trojan horse by Strongylion, with Menestheus and Teucer, Demophon and Acamas looking out from his side, two works of which we have the bases only. One cannot but wish that we could restore the group which represented Athena leaping full-armed from the head of Zeus, or the bronze Theseus lifting the natural rock to recover his father's sandals. One cannot but long for an hour in the Pinacotheca, amid the paintings of Polygnotus and Aglaophon, so infinitely removed from the superficialities and vulgarities of Pompeii. These things are gone for ever, and it is perhaps a poor consolation to know that we have of late become better able to appreciate their loss.

The Palace at Spalato and St. Sophia.

At Spalato the movement of new life was first felt. There is much about the building that is downright ugly, still more that is but a mass of worn-out tradition; but there, first, as far as we know, is visible the attempt to throw off the swathings of ill-understood Greek art, with which Roman architecture had encumbered itself, and to make that architecture reasonable and consistent with the living principles of art. But at Spalato, though the art was trying to be alive, it was scarcely alive, and what life is in it is shown in its construction only and not in its ornamentation. St. Sophia, early as it is in the history of the art, has utterly thrown aside all pedantic encumbrances, and is most vigorously alive. It has gathered to itself all these elements of change, which, having been kept apart for so long, were at last mingling and seething, and bringing about so many changes—so much of death and life. It is not bound by the past, but it has garnered all that there was in it which was fit to live and produce fresh life; it is the living child and the fruitful mother of art, past and future. That, even more than the loveliness which it drew forth from its own present, is what makes it the crown of all the great buildings of the world. The new-born art was long in coming to this. Spalato was built about 313 A.D., St. Sophia in 530. More than 200 years are between them, by no means fertile of beautiful or remarkable buildings; but St. Sophia once built, the earth began to blossom with beautiful buildings, and the thousand years that lie between the date of St. Sophia and the date of St. Peter at Rome may well be called the building age of the world.

The Study of Art.

Every one may perceive from the numerous discoveries made of late in the physical world, and which, by-the-by, are characteristic of the age, how necessary it is to occupy oneself with the concrete, with the particular in science, in order to arrive at just conclusions when regarded as a whole. And from the wonderful manner in which all things are intimately connected such investigation becomes a double gain, for while we fathom the nature of the one component part, all the rest become illumined and more intelligible. And thus it is with art. Here the concrete is the work itself. What, then, have we to do? To leave the abstract idea of art, and, occupying ourselves with the form in which it now appears to us, the

individual work, namely, which a free poetical imagination has brought forth, to endeavour here to find again and comprehend those vital principles on which the conception of art, taken generally, is founded. The peculiar shape it assumes will, of course, depend on the particular province of art and the general laws of that province in which it may appear. But be it what it may, in it will always be, modified according to circumstances, what may be termed the pervading thought of the whole. But it is just in the form which it assumes, the outward form as perceptible to our senses, that this pervading thought shows itself. The first requisite, therefore, of the philosophically investigating mind is to be able to lift this "concrete thought" from out the world of living forms, and to retain it with a firm grasp. That this would be considered by many as too hard a demand we are well aware of, and is a circumstance we shall allude to later. "It appears to us no unfitting image," says Röttscher, "if we compare this first moment of philosophical activity in the treatment of the work of art to a breaking to pieces of the form by which really the beautifully conjoined structure is for the moment decomposed. At first the whole man is possessed by the work of art, and is, so to say, satiated by its abundant fullness; but as a spiritual being he feels the profounder necessity of arriving at a consciousness of the nature of his delight, and thus to sanction it to himself. This very spirit, then, necessarily impels him to break the costly vase in order, undazzled by its splendour and beauty, to gaze on it in its purity." "The beautiful body of the work of art is therefore to be destroyed in order to find its beating heart. By so doing the thinker takes the place of Minerva, who from the body of Dionysus Zagreus, torn in pieces by the Titans, saved the still palpitating heart. And it is particularly for the preservation of this vital part, and with it the vitality of the whole, that all activity is to be exerted." And the doing of this is the first important act in the process so begun. But as when by means of refraction we have unravelled the composition of a sunbeam, we afterwards give it back its pristine unity that it may shine on in all its genial warmth and vivifying power, so the form, which for a moment has been broken, must be again restored. The spirit which banished itself voluntarily from the land of beauty and from the circle of living forms now returns, in order, with a feeling of self-consciousness, to live in this world and understand its language and its sounds. The two are now again united, as intimately united as the soul and body in the breathing man. But, unlike a body of too solid flesh, this one is subject to none of the ills which disturb the calm of the mortal frame; it has no nerves and tendons, it is one which has acquired this positive form by the power of artistic enthusiasm, and, by its plastic faculty, a form of which it may be said "it has cast aside every evidence of human neediness."

Comprehensiveness in Painting.

One of the observations of Sir Joshua Reynolds is that it is by the power of drawing correctly what we see that we are enabled to draw correctly what we imagine. The principles of art are simple and fixed, and they are compendiously enunciated for the student's use in the great examples which the sculptors and painters have left. These results have a classification determined to a great extent by the nature of the materials with which they work. Principles of proportion and form have been deduced from sculpture; those of colour, of light and shade, and of composition have been established on the labours of the various schools of painting. In the works of three of the greatest masters of the painter's art whom the world has produced, severally conspicuous each for a quality of his own—Raphael, Titian and Rembrandt—we may illustrate alike this principle of comprehensiveness in seizing what are the main or predominant characteristics. To begin with Raphael. If we take for our purpose his most accomplished works, the Cartoons, we find on examination that so many details only are given of the human form or draperies as are absolutely essential to the just description of the parts, or are indispensable to their action. By testing this principle of comprehensiveness in arranging draperies, we shall find how many forms in the draperies that were extraneous and unessential to the expression of the human form beneath have been omitted by the great artist. So Titian omits all trivial particulars in representing a mass of flesh-tint. The eye at once recognises the general truth of the part, and is unfatigued by a sense of the elaboration that suggests exertion or great painstaking. In fact, the eye is impressed in exactly the same way as on beholding Nature herself. If we inspect the picture more minutely, we behold a fusion of the tints, corresponding to that which we see in the real flesh and those local peculiarities of colour in particular parts of the limbs, which do not interfere with the general sense of truth or the prevailing air of simplicity of means. Rembrandt, with his light and shade, arrives by different means at imitative results similar to those of Titian. With a power of calculation that controlled every seemingly rude touch to a definite end, distance from the picture is all that is needed to make these singular means combine in the revelation of character, of expression, or of gradation in light

and shade. Rembrandt's production of these results is as much under the control of abstract principle as ever were the linear treatments of a Greek sculptor. Reynolds, in his "Ugolino" and in other historical presentments, combining often the characteristics of Titian with those of Rembrandt, indulged in that degree of imitation which never distracts or divides the attention between the picture in its subjective and objective truth and any personal display of his own powers.

Hogarth and Academy Exhibitions.

It is a somewhat singular circumstance that as Hogarth throughout his life uniformly opposed the establishment of a public academy of arts, he should, by the very course he pursued in encouraging and concentrating at the Foundling Hospital an exhibition of the talents of British artists, have himself promoted a consummation of the object which he had all along deprecated. "In consequence," says Nichols, "of the public attention bestowed upon the paintings presented to the Foundling Hospital by Hogarth, the Academy in St. Martin's Lane began to form themselves into a more important body, and to teach the arts under regular professors. But, extraordinary as it may appear, this scheme was so far from being welcomed by Hogarth, as indicative of a brighter era in the fine arts, that he absolutely discouraged it, as tending to allure many young men into a profession in which they would not be able to support themselves, and at the same time to degrade what ought to be a liberal profession into a merely mechanical one."

Classic Innovations.

In our admiration of ancient architecture we must not be too indiscriminate; the ancient architects were, after all, but fallible men; some indeed among them were strongly endowed with the perception of what was grand and noble in their art, while others were feeble imitators or tasteless innovators. The principles of Grecian architecture, those principles which were sanctioned by an Ictinus or a Callicrates, we may safely follow, but all the practices of individual ancient architects are not to be accounted of equal authority; in Italy many dangerous precedents exist, most of them probably belonging to a period when architecture as well as sculpture was rapidly declining. One instance is found in the high pediment of the Pantheon at Rome, a building to which at the same time we are greatly indebted for setting the example of the beautiful domes which adorn so many of our modern churches. Other ancient Roman buildings, particularly their triumphal arches, gave examples of breaking the entablatures into small portions, a part projecting over each column or pair of columns, thus entirely destroying the great bond of unity in the edifice, as well as preventing the fine effect produced by the depth of shade which a broad and continued entablature casts. Another innovation of the ancient architects on the simplicity of the principles of their art was the piling of order on order, and the mixing together what was essentially distinct: that this innovation was sometimes productive of a good effect cannot be denied; after the example of the Coliseum it would be idle to do so; but undoubtedly it was dangerous, and its imitation has introduced much confusion and deformity into the art; indeed this innovation may plead in its defence some very plausible arguments, from the obvious necessity of giving greater lightness to the upper and greater solidity to the lower parts of the building, as well as the propriety of marking in some degree the nature of the internal arrangement, by the division of parts on the exterior of an edifice. The latter argument has indeed more of apparent than real force, as all that is really necessary is that an edifice should not, by its imposing exterior, excite hopes of internal magnificence to be afterwards disappointed. The placing of columns on pedestals was another innovation, first introduced perhaps from necessity in the Roman triumphal arches; this is destructive of the fine effect of a flight of steps or continued basement, uniting as a bond the building together below, in the same way as it is united above by the entablature; it has besides the further ill effect of changing entirely the proportions of the pillars, as a separate pedestal is, in fact, nothing more than a monstrous base or plinth to the column which stands upon it. Another ancient innovation of no frequent occurrence was the spiral fluting of columns; this practice is inconsistent with the essential principle of straight lines which pervades Grecian architecture, and from its very nature introduces a degree of crookedness and of apparent weakness, which has a very disagreeable effect. This effect the ancients appear to have endeavoured in some degree to obviate by turning the spiral line of a pair of columns in opposite directions, thus opposing one weakness and one obliquity to another—a contrivance which reminds us of the beauty of a person who squints with both eyes instead of one. The Roman Doric, Tuscan and Composite may be considered as meritorious inventions rather than innovations, properly so-called. The Grecian or genuine Doric is certainly superior in grandeur and majesty to its more recent rival, but the latter has some capabilities not possessed by the former.

The Carrara Marble Quarries.

The quarries of Carrara contain four varieties of marble, of which the most valuable is that used by sculptors, the white granularly foliated limestone. This has always been the favourite material both of the artists of ancient Greece and of modern Europe, in consequence of its purity of colour, its delicate transparency, and its granular texture, which renders it much more easy to work than compact limestone. The two great sources whence the statuary marble of Europe has been procured are Paros and Carrara. The Parian marble is the most pure, consisting almost entirely of carbonate of lime, and is, consequently, softer, somewhat more transparent, and of a more visibly laminated texture than that of Carrara, which is frequently mingled in considerable proportion with granular quartz. The latter has, however, no other rival as regards either quality or durability. The other three varieties obtained are the "veined" marble, equal as regards texture to that already described, but traversed by coloured lines which render it inappropriate to the chisel; the "ravacioni," or Sicilian, similar to that produced near Messina; and the "bardiglio," which is of a deep blue colour, but in formation precisely similar to the white. Some of the quarries may be explored with ease and safety, but such is by no means the case with all of them; while, in every instance, the paths by which they are approached are full of peril to the uninitiated. In working the quarries, the huge blocks are first loosened from the mass by blasting, after which wedges are applied until they are thoroughly detached from the rock, when they are shaped into oblong squares, with the exception of the statuary marble, of which the value is so great that the masses are removed intact, then lowered to the *poggio*, or base of the mountain, whence bullock-cars transport them to the Marina, where they are embarked. When the quarry is situated so perpendicularly that the stones incur risk of breakage from a too rapid descent, they are securely surrounded by strong ropes, and placed upon two parallel beams (or *lizzi*) of oak, beneath which lesser beams are arranged transversely. A workman stands upon the block throughout its perilous transit, whose duty is to raise each of these so soon as it is passed, and to hand it to another man in front, in order that it may again be placed securely upon the passage of the descending mass. This is the most dangerous service performed by the miners, as it occasionally happens that the huge block, after shivering for an instant upon its wooden support, yields to the impetus of its own weight, and, sliding from its oaken cradle, rushes headlong down the declivity, rending the stout cables by which it is bound like whipcord, and crushing beneath its stupendous mass the unfortunate individuals employed in assisting its descent. Where the quarry is level, and nearer to the base of the mountain, the *lizza* is dispensed with, and the blocks are allowed to roll down unaided. This operation at times produces a most beautiful and thrilling spectacle, and one of so wild a nature that no description could do it justice. At the *poggio* the blocks thus collected are loaded upon strong, uncouth-looking bullock-cars, composed of three parallel beams of oak, of which the centre one is rather lower than the others; the animals are attached to the carriages in numbers proportioned to the bulk of the stone and the impediments which encumber their path, and the scene which ensues is one of the most extraordinary character. It is a very common occurrence to see ten yokes of oxen harnessed to one car, each guided by a driver, whose business it is to avoid as much as possible the ponderous masses by which the ground is overstrewn.

Early Photography.

It is tolerably certain that in the sixteenth century the darkening of horn silver (fused chloride of silver) was observed by the alchemists, but it was not until the eighteenth century that any examination of the phenomenon was made. Even then the influence of light on the crystallisation of salts first attracted attention, and memoirs on this subject were published by Petit in 1722, by Chaptal in 1788, and by Dizé in 1789. In 1777 Scheele, the celebrated chemist of Sweden, writes:—"Fix a glass prism at the window and let the refracted sunbeams fall on the floor. In the coloured light put a paper strewn with luna cornua, and you will observe that this horn silver grows sooner black in the violet ray than in any of the other rays." Senebier in 1790 ascertained that this white salt of silver darkened in the violet ray in fifteen seconds to a shade which required the action of the red ray for twenty minutes. In 1801 Ritter, of Jena, demonstrated the existence of rays beyond the spectrum, having no illuminating power, but possessing active chemical properties. A similar set of researches were undertaken by Dr. Wollaston about the same time, which also proved the remarkable differences existing between the differently-coloured rays. These researches led the way to the experiments of Wedgwood, the celebrated porcelain manufacturer of Etruria, in Staffordshire, which, beyond all dispute, must establish him as the first photographic artist. From the *Journal* of the Royal Institution of 1803 we copy the title of Mr. Wedgwood's memoir and a few of his remarks, with the

notes of Sir Humphry Davy:—"An Account of a Method of Copying Paintings upon Glass and of Making Profiles by the Agency of Light upon Nitrate of Silver; with Observations by Humphry Davy." A solution of nitrate of silver spread on white paper or white leather was the photographic material employed, and he remarks:—"The alterations of colours take place more speedily in proportion as the light is more intense. In the direct rays of the sun two or three minutes are sufficient to produce the full effect; in the shade several hours are required, and light transmitted through different coloured glasses acts upon it with different degrees of intensity. When the shadow of any figure is thrown upon the prepared surface the part concealed by it remains white, and the other parts speedily become dark. For copying paintings on glass the solution should be applied on leather, and in this case it is more readily acted on than when paper is used. After the colour has been once fixed on leather or paper it cannot be removed by the application of water or soap, and it is in a high degree permanent. Besides the applications of this method of copying that have just been mentioned, there are many others, and it will be useful for making delineations of all such objects as are possessed of a texture partly opaque and partly transparent. The woody fibre of leaves and the wings of insects may be pretty accurately represented by means of it, and in this case it is only necessary to cause the direct solar light to pass through them, and to receive the shadows upon prepared leather." Sir Humphry Davy adds:—"The images formed by means of a camera obscura have been found to be too faint to produce in any moderate time an effect upon the nitrate of silver. To copy these images was the first object of Mr. Wedgwood in his researches on this subject. In following these processes I have found that the images of small objects produced by means of the solar microscope may be copied without difficulty on prepared paper. In comparing the effects produced by light upon muriate of silver with those produced upon nitrate it seemed evident that the muriate was the most susceptible. Nothing but a method of preventing the unshaded parts of the delineation from being coloured by exposure to the day is wanting to render this process as useful as it is elegant." No further investigation of the subject appears to have been made for many years. The failure on the part of Wedgwood and Davy was due entirely to the want of these chemical agents, which were afterwards employed as the fixing materials. Hyposulphite of soda was not discovered by Sir John Herschel until 1819, when he at once detected and described the habitudes of the salts of silver in connection with hyposulphuric acid. Iodine was not known before 1812, when it was discovered by Courtois, a manufacturer of saltpetre at Paris, and bromine was a yet later discovery by M. Balard, of Montpellier. Without these agents photography could not have advanced beyond the point at which Wedgwood and Davy left it.

Botany and Art.

It is the duty of the artist to study congruity in the vegetable forms he brings together, to place every plant in a natural situation, and to imitate the general outline of plants correctly. Some knowledge, of botany is required to enable him to do so with confidence, and the greater his acquaintance with the science the greater will be his capacity for imparting variety to his scenes, without trenching on their truth to nature. But when the artist has to compose a group of small extent where a few figures are represented of a large size in a limited space so near the eye of the spectator that every feature and emotion of the countenance is a part of the picture, then, whether it be a sylvan or a garden scene, there cannot be too faithful a representation of surrounding objects. The simple trunk of a tree has its character, varying with the species—the stem of the oak, of the pine, of the beech, or of the birch—each has its own peculiar surface to be studied by the artist, not to speak of the widely different ramification and foliage of those trees. And so also, and in a greater degree, of the small plants in the foreground. The commonest way-side weeds have a picturesque character. But how seldom do we see a bramble or a wild rose naturally represented, or even a thistle or a dock. The things that figure in many modern pictures for brambles or roses (where the artist is so far ambitious as to attempt a definite representation of them) have no prototype in nature, and would simply remind us of the ornaments of Christabel's chamber, which were "All cut out of the carver's brain," save that they are deficient in the grace and delicacy of the great fancies described by the poet. Surely we want a Wilkie or a Teniers for our woods and hedges, to picture faithfully the wildings of nature. If a stable-yard and a village alehouse can be refined into a graceful picture, how much more might the thousand picturesque nooks of our island supply subjects to the artist who would be contented to study them minutely, and still with freedom, not in the servility of a mere copyist. Even a subject so homely as the garden of the sluggard, where "the wild briar, The thorn and the thistle grew broader and higher," painted with botanical truth and in a genial spirit, would form no bad picture.

NOTES AND COMMENTS.

THE establishment of a school of architecture in connection with Liverpool University College is under consideration. It was decided that a scheme should be drawn up showing details of requirements and expenditure, that the County Council should be approached with an application for funds, and that the following motion should be recommended for the acceptance of the Senate:—"That in the event of funds being secured for the establishment of a school of architecture, providing an architectural studio, a life school and a studio for modelling and sculpture under the management of efficient teachers, the Senate recommend the allocation of the remainder of the Art Chair endowment (say 225*l.* per annum) towards the remuneration of a teacher in drawing from the life." The estimated outlay is 1,250*l.* a year. That would be a large addition to the expenses of the college. As the advantages would be mainly the providing of assistants for the local offices, it is hoped the Liverpool architects will exhibit their interest in the experiment by subscribing liberally towards the expenses. At present they do not appear to have contributed a penny, although they are so anxious to derive profit from the architectural school.

SURREY is one of the smaller English counties, but in the past, as in the present, it was of more importance than many of the larger shires. The volume on "Bygone Surrey," edited by Mr. CLINCH and Mr. S. W. KERSHAW, M.A., which is now in the press, should therefore be of absorbing interest, for it is to treat of history, antiquities, industries, local customs and folk-lore. As the editors say, "Well nigh every parish has its ancient church, sometimes rich in colour decoration, consecrated by holy memories and associations with the past; and quaint, half-timber houses and cottages exist throughout almost the entire area of the county. Ruined castles and religious houses, ancient ways and roads (including the remarkable Pilgrim's Way), relics of prehistoric times in place-names and traditions, as well as curios and old-world customs, are among the various antiquarian features which characterise the story of 'Bygone Surrey.'" When the materials are so abundant it will be easy for the contributors to produce a book that will be valuable. Reproductions of old engravings relating to Surrey will add to the attractions of the pages.

SPALATO in Dalmatia is interesting to architects on account of the Palace of Diocletian, which according to some theorists is one of the most important buildings of the world. The ancient Palatium has much else to show to travellers, and few cities are more suggestive of the utilisation of ancient buildings and their materials for modern uses. Like the rest of the world Spalato has become convinced of the advantage of conferences. It is therefore proposed to hold one this year, probably in the beginning of September. As the subject to be considered is Christian archaeology in all its branches, it has, of course, universal interest. The arrangements for the conference will depend in a great measure on the number of archaeologists who are willing to take part in the proceedings by reading papers or in other ways. It is therefore requested by the promoters that gentlemen who contemplate visiting Spalato, or are willing to aid the congress, will communicate with Professor FR. BULIĆ, the director of the museum and editor of the *Bullettino di Archeologia e Storia Dalmata*, who is acting as secretary, who will be glad to give information. On the committee are Professors NEUMANN and SWOBODA, of Vienna, Monsignor DE WAAL, of Rome, and other specialists. The experiment is novel and cannot fail to receive support.

THE Lower Greensand formation has just been found at the depth of 1,234 feet below the surface, in an artesian boring at New Lodge, Windsor Forest, being made by Messrs. LE GRAND & SUTCLIFF, hydraulic engineers, of Bunhill Row, London. The chalk was struck at 214 feet and found to be 725 feet thick, beneath which there was 31 feet of upper greensand, followed by 264 feet of gault. Hitherto all attempts to find the water-bearing lower greensand under the London basin, which in Kent and Surrey varies from 200 feet to 300 feet thick, have met with no success; but in the present case a problem of great interest

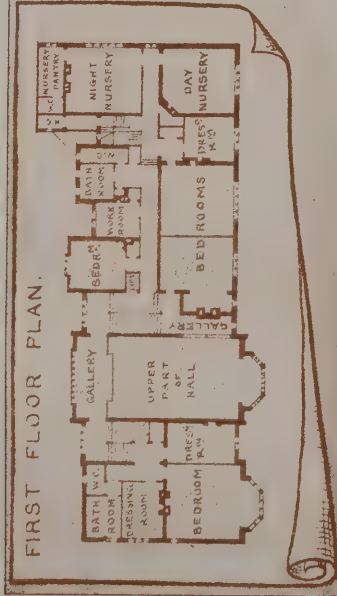

has been solved, for after penetrating only 9 feet into it, viz. at a total depth of 1,243 feet, a fine spring has been tapped and has risen to over 7 feet above the surface, though the site of the boring is 203 feet above the sea-level.

A COMMITTEE of the London County Council, accompanied by Mr. SHIRLEY MURPHY, M.D., the medical officer of health, and Mr. SANTO CRIMP, M.Inst.C.E., engineer, visited the Highgate Museum of Sanitary Appliances on Wednesday, and were met by Mr. H. R. WILLIAMS, chairman of the Hornsey Local Board, and Mr. T. DE COURCY MEADE, M.Inst.C.E., the engineer to the Board, by whom they were conducted over the Museum. The committee were greatly pleased with the numerous objects of interest which the buildings contain, particularly with the sectional model of a sanitary dwelling, and the appliances for ascertaining with some degree of accuracy the flow of air through pipes used for ventilating house drains when fixed under varying conditions. This arrangement of pipes very clearly demonstrates the necessity for avoiding, as far as possible, all bends in the up-cast or extracting shafts, as well as in the drains themselves. The latest improvements and inventions in sanitary work are constantly being added to the already extensive store of information contained in the buildings, and the fact that the Museum has been visited by 8,000 persons since the beginning of this year speaks well for its future sphere of usefulness. It was thought that if such an institution were established by the Council much good would result. The committee complimented Mr. WILLIAMS on the excellence of the collection.

THE appointment of Professor MIDDLETON, of Cambridge, to the directorship of the South Kensington Museum (art division), in succession to Sir P. CUNLIFFE OWEN, is another sign that "My Lords" have awakened to the necessity of seeking outside aid if the Department's work is to be efficiently conducted. The system of raising a high class of officials in the offices at South Kensington has been a failure that is notorious, and it had to be abandoned or the administration must collapse. The days for placing lackeys in the most responsible positions have, we hope, passed away for ever. The new director has no easy task before him. To apply a common expression, we may say that the Museum is not in touch with the schools or the country. The students are not instructed in the way of making use of the collections, and there is no doubt foreigners derive far more advantage from the objects exhibited than the English people. Professor MIDDLETON will no doubt be eager to see his countrymen turning the treasures to account, but that is impossible unless there is a change in the system of instruction in the schools, and his interference in that direction would be resented. One thing he might try to do, and that would be to make some of his assistants obtain as much knowledge about the things exhibited as is now possessed by the constables on duty.

THE London Chamber of Arbitration is a success. According to the chairman, there has been a sufficient number of cases to test the organisation, and those disputants who have had recourse to it speak well of the simplicity, the rapidity, and the efficiency of its machinery. In some of the cases professional representatives have been employed, but the majority of disputants have conducted their own cases. Disputants have submitted to the arbitrator in some instances an agreed statement of facts, and thus dispensed with personal attendants. So far one case only has been referred to the chamber by the High Court, and the expedition with which the case (involving much technical knowledge) was heard and decided elicited expressions of satisfaction from the Court. In about half the cases the selection of the arbitrator has been left to the registrar, and in no instance has more than one arbitrator been employed. Arbitrators have had the legal aid of the registrar in drawing up their awards, save in one case, and then the award was referred back owing to a legal technicality. The arrangements of the chamber, however, are designed to prevent such occurrences. Hearings have taken place on an average within ten days of the submission being lodged, and their duration has averaged two hours; the fees have averaged 5*l.* 12*s.*

HOUSE AT WITMEAD, NEAR FARNHAM.

THIS house is about to be erected near Tilford, for Colonel DAVIS; a lodge already built was illustrated in this Journal last year. A basement, containing larders, cellars, heating chamber, &c., will be built of concrete made of gravel dug on the property and selenitic lime; the latter is also used for all mortar. The building generally will be of red brick in hollow walls, with weather tiles on the south-west side, and Beer stone mullions and dressings to hall and entrance windows, &c.; local red tiles set in concrete plaster will be used for the roof. Advantage is to be taken of a rapid fall in the ground to form a spacious terrace in front, with flights of steps descending to the tennis-grounds and the ornamental water connected with the river Wey. The side, with main entrance, faces north-west, and the front with terrace south-east. The architect is Mr. RALPH NEVILL, F.S.A., of Rolls Chambers, Chancery Lane.

PART OF OLD PALACE, BAMBERG.

THE ARCHITECTURAL ASSOCIATION.

THE ordinary meeting of the Association was held on Friday evening last, Mr. H. O. Cresswell, president, in the chair.

Mr. GUY DAWBER read the following paper, entitled—

The Stone Buildings of the Cotswolds.

The particular portion of the Cotswold Hills to which I wish to draw your attention this evening is the small area bounded by Cheltenham and Winchcombe on the west, by Chipping Norton and Moreton-in-Marsh on the east, by Broadway and Campden on the north, and Northleach and Cirencester on the south. In appearance these wolds have a gentle down-like aspect, falling at intervals into valleys, the sides of the hills abounding with springs. Villages, farms and manor-houses are plentiful, and the country is well-timbered, beech and elm growing specially well.

In these short notes I will not attempt to tell you of the history of these hills—how rich they are in Roman remains. There are everywhere traces of Roman occupation. The Fosse way—one of the most perfect of Roman roads—enters Gloucestershire near Moreton-in-Marsh, and runs in a direct line over hill and dale, through Stow-on-the-Wold, Northleach, and out at Cirencester, once a great Roman station. The beautiful remains of the villa and Roman baths at Chedworth, some few miles from Northleach, are well known. A great portion of these remains are in a perfect state of preservation.

Under the Heptarchy, this county formed the western part of the extensive kingdom of Mercia. Winchcombe and Kingstunley were residences of its kings. This country is also interesting from its close connection with the Parliamentary wars, many of the villages and houses having legends and tales concerning them. At Donnington, a little hamlet lying near Stow-on-the-Wold, the king's forces, under Lord Aston, were so completely defeated by Colonel Morgan in March, 1645, that all hope of maintaining the garrison at Oxford was abandoned. At Bourton-on-the-Hill was born Sir Thomas Overbury, whose death by poison is recorded in the parish register in 1613. Amongst other interesting entries it is also recorded that on October 10, 1666, the parishioners collected a fund of 6s. 8d. "towards the late fire at London."

At Compton, some four miles from Moreton-in-Marsh, are the remains of Archbishop Juxon's manor-house, erected in the early part of the seventeenth century.

Chastleton Hall—not exactly on the Cotswolds—is a very fine house with a courtyard. It is full of most interesting work and detail, having excellent door and window fittings and panellings. The long gallery is a charming room with a barrelled plaster ceiling, panelled in oak up to the springing line. This oak was partly painted and gilt, as is the case at Haddon Hall and other places.

Geologically the Cotswold Hills form a portion of the great belt of limestones, which extends across England from the Dorsetshire coast to a point between Filey and Scarborough. They form an elevated tableland or plateau some 800 to 1,200 feet above sea-level, presenting a steep escarpment facing west to the valley of the Severn.

This escarpment was perhaps a cliff range overhanging an arm of the sea, and the tableland behind has since been cut into valleys by frost, rain and brooks, and swept completely bare of the gravels which lie so thick in the valleys beneath. The strata dip slightly to the south-east and east, and comprise the whole of the oolitic series, a vast mass of more or less continuous beds of limestone, separated by partings of clay, all of marine origin, and enclosing in places vast amounts of shelly matter, such as beds of oysters or reefs of coral.

To architects the whole formation is of unusual interest, as within its limits are found almost all the building limestones used in England. The series commences with the inferior oolitic limestones, which stretch from Bridport northward to Beamister and Sherborne, and broadens out on the flat-topped Cotswolds east of Cheltenham. It is succeeded by a band of the clayey substance, "Fuller's earth." This forms a water-bearing zone amongst the hills, which would otherwise present many arid and barren tracts. The great or Bath oolite has at its base the well-known Stonesfield slate, which splits into coarse fissile slabs, used for roofing purposes.

The main body of the great oolite caps the hills round Bath and ranges over the Cotswolds, where it is very largely quarried. The middle and lower beds are the best stones for building purposes, soft when first quarried, but possessing the well-known property of hardening under exposure.

The stone in the immediate district I am speaking of is quarried from about April to October, after which the quarries are closed for the winter months. It is generally obtained by clearing away the upper layers of inferior stone and earth, and is not mined for, as most of the Bath stones. When fresh quarried it is of a pale lemon colour, which bleaches by exposure, and after a time turns to all manner of rich colours, and quickly becomes covered with lichens. It is an excellent weather stone, as the work in the district testifies. Nearly every village has its local quarry, but the best stones are Bourton Hill, Westington, Windrush, &c., in the immediate district of which I speak.

Owing to the nature of the formation of these hills, and stone being practically the only material usable, we cannot but admire the ingenious way in which the builders used it in almost all their work. The country roads are metalled with it, and bad roads they are as a rule, unless mixed with a harder stone. The fields are divided by stone walls, mostly laid dry, with small stones most ingeniously fitted together—in fact, in a wall properly built it is almost impossible to pull out a stone. The cattle-troughs, gate-posts—in fact, everything for which stone can be adopted are made of this material.

The houses generally are simple in plan and not badly arranged, and in the larger houses, those occupied by the yeomen or farmers, the plan is generally elongated, with a large central hall or reception room, a kitchen on one side, and dairy, &c., beyond, and a general living-room on the other. The stairs lead out of the hall or a passage behind the hall to the bedrooms, nowadays changed to rooms opening off a passage, but formerly opening one out of the other. At this period it was thought injurious to sleep in rooms facing the sun, so most of the original rooms face the north and east.

Mr. Baring Gould says in his "Old Country Life":—

At the head of the stairs slept the squire and his wife, and all the rooms tenanted by the rest of the household were accessible only through that. The females, daughters of the house and maidservants, lay in rooms on one side, say the right, the maids in those most distant reached through the apartments of the young ladies; those of the men lay on the left, the sons of the house nearest the chamber of the squire and the serving-men furthest off.

As a rule the houses—the cottages and manor-houses, and indeed all the larger ones—were built during the seventeenth century or early part of the eighteenth. It is rare to find them much earlier than the last years of the sixteenth century, and this is probably owing to the fact that during the seventeenth century there were more resident gentry in the country than at any other period, and that they mostly lived on the produce of the land, and were not, as a class, at all wealthy.

Naturally these people would encourage building, and, no doubt, their example helped to form the taste of the people and inhabitants of their estates. Hence the uniformity of feeling in the work of this period.

When in the reign of Queen Anne the trade of the country developed, and great fortunes were rapidly made in commerce, many of the landed gentry who had become impoverished, first by the civil wars, and then by the extravagance of the Restoration period, sold their estates and went to live in the country towns and cities. The wealthy business class, who occupied some of these old houses, not being indigenous to the soil, did not take so much interest in the village folk and community at large, and chiefly expended money on their own houses, not having direct ancestral interest in the villages, and so to a certain extent neglected them.

Even in later times, when the labouring classes became very poor, it was no uncommon occurrence for them to be turned out of their villages and their cottages pulled down, so that they

should not become a burden on the parish and the landowners. You will note that nearly all these stone buildings are of the seventeenth century, and in this district you will often find entire villages built during this period with hardly a house of later date, except perhaps one or two erected within the last fifty years. They are nearly always built of rubble stone walling, sometimes coursed, but more generally not, and have dressed angles and stone mullioned windows, &c. The stone laminates freely, and hence there was no difficulty in obtaining walling stone. The walls are thick, 2 feet and more in many instances, and delightful window-seats and nooks are obtained in this way, as the mullioned windows being on the outer face of the wall, the whole depth was given to the room. In some situations these thick walls hold the wet and damp to a very great extent. As a rule, however, they are absolutely dry. Horizontal damp courses were unknown when these houses were built, and the floors were generally of stone laid direct on the earth, unless there were cellars underneath. The upper floors were generally of thick joists pugged solid between with lime and chopped straw.

In Campden, a most unique country village, are some excellent specimens of this period from parts of the court-house, built in the fourteenth century, to houses of the latter end of the last. The old market-house in the centre of the main street was built in 1624 by Sir Baptist Hicks, a former mayor of London, and a great benefactor of the town. One house of the fifteenth century, with a beautiful bay window, carried up two storeys, was the residence of the Greivilles, who were wealthy wool merchants in the fourteenth and fifteenth centuries, and whose memorial brasses are in the church. This now decayed town was full of life and activity, and had a very large wool trade with Flanders—the sheep being raised on the Cotswolds surrounding, and the wool being sent abroad.

I know of no more interesting county town in all England than this, or a more picturesque sight than the main street, with its small islands of building, as it were, dotted about, breaking the continuity of the street, and giving a charming variety to the perspective. Adjoining the church, on a raised terrace overlooking undulating fields and hills, are the remains of a house once inhabited by Baptist Hicks, which was burned down during the Parliamentary wars. At either end of this raised terrace are pavilions. There is a great similarity between the mouldings of these terrace pavilions and those of the Kite's Nest, a manor-house near Broadway, some seven miles off—a house that contains amongst other interesting details a truly magnificent oak staircase, with massive turned balusters and solid newels. These houses were evidently built by the same hands and carried out at the same time, as they are rather later in character than the usual work.

The roofs of all these houses are treated in a similar manner, high pitched at about an angle of 55 deg., nearly all covered with the small stone slates of the district, or else thatched, but this is probably a substitution for the slates in later times. It is rare in this part of Gloucestershire to find the large, thick Forest of Dean slates, and to my mind the small ones are infinitely superior both in appearance and suitability. They are graduated in size and thickness from the eaves to the ridge, where the thinnest are placed.

They are covered always, in the old work, by a stone cresting, generally of plain section, and are hung with oak or deal pins over laths.

Owing presumably to the difficulty of procuring lead the builders of these houses turned their attention to methods of doing without it, and so we find the houses generally so planned that they can be roofed in a single span. Hips are extremely rare. There are always gables with the coping projecting well over behind, the slates tucked close under and pointed flush. The chimneys, too, have a projecting weathering at the bottoms, following the rake of the roofs, and are nearly always arranged centrally over the ridge. The valleys, where one would naturally expect to see lead, are formed of slates in a wide sweep, laid on the curve just as the other portions. The eaves in most of the work project well out on a moulded or splayed stone course, and have no eave-gutters—a bad plan, as the water soaks into the foundations and makes them damp.

The method of procuring these slates is worth noting. In October a piece of ground at the quarry is measured off, and the top, 8 feet or 10 feet of loose stuff, is cleared away. This process is called "ridding." The stone for the slates is then uncovered, and is called "pendal." It is dug out and wheeled to the top of the ground, laid down flat, and roughly fitted one piece into the other as well as it will allow. It lies then all through the winter exposed to the frost in thicknesses of from 2 inches to 12 inches or 14 inches. Owing to the beds of natural moisture in the "pendal" the frosts swell these, and in a thaw a few blows of a hammer separates the layers. When this splitting is done they are squared and cut into sizes and are ready for use, but should there be no frost there are no slates, and the stone must wait for the following winter.

For stone houses there is no more beautiful or suitable material than these stone slates. Even when brand-new they

are beautiful in colour, being of all shades of greys, yellows and blues. To see the old houses, with roofs covered with lichens, and the richest colours conceivable, all harmoniously blended, is charming. If properly seasoned at first they will stand for centuries, and no frost or wet will touch them afterwards.

It seems difficult to understand, with such material in this district, that blue slates, and even galvanised iron—material wholly out of harmony with the building—should be employed. Yet so it is, the excuse being that the stone slates are more trouble to hang and want occasional repairing, in spite of the fact that before one's very eyes are old houses and barns two hundred and more years old still covered with the original roofs. It seems unreasonable to go miles afield to obtain an inferior material, when a better one lies literally at one's feet.

Another matter I should like to draw your attention to is the variety of the stone gable terminations and finials. These latter are especially worthy of note. In no district in England is such a wonderful variety of detail and form to be found.

In Chastleton Hall are many good examples, and in Broadway and Campden and Moreton-in-Marsh they are especially interesting, being pierced and cut in a really marvellous manner. These finials are generally placed on the apex of the gables, but many are also on the springers and knee-stones. As an instance of the way tradition lingers in country places, even in these prosaic days, you may note corn-stacks thatched, with the apexes carried up, and open work finials in twisted and woven straw of infinite variety, showing the influence of the stone treatment in this district.

The windows are nearly always treated in the same way, with stone mullions and narrow lights, about 18 inches from centre to centre, with stout chamfered ovolo moulded mullions, and with labels over the heads, or else a moulded string. Except in the larger houses, transoms and upper lights are uncommon.

The doorways vary. They have either the four-centred arch, such as you will notice on the photograph of Campden Almshouses, or else a square head, with very deep lintel and moulded jambs.

In Broadway is a peculiar instance of the transition from the Tudor to the Jacobean style. The outline of the doorway is distinctly Gothic, having a four-centered head and leaves in the spandrels, but the detail is classical, with dentils worked all round it and down the label moulding.

The roofs are frequently broken up with dormers, and these are treated in various ways, as you will see in the photographs exhibited.

The chimney-stacks are invariably carried up solid until the roof is well cleared, when the flues are treated separately, either square or diagonal on plan, and the cap ties them together at the top. This, however, was the general method of treatment throughout England at this period.

In connection with the windows I must speak of their fittings and their delicate and refined ironwork. Many beautiful examples of these I show you to-night, both in the actual metal and in drawings. Great time and care were spent in the seventeenth century on the furniture of the doors and windows, and some of the iron casement fastenings in these Cotswold villages and houses are beautiful examples of the smith's work. When one considers that these houses were occupied and built for the yeomen and ordinary workers of the land, and that in the humblest cottages fastenings as delicate as the examples I exhibit are found, it grieves one to think that such work in such situations is unheard of in modern buildings. All of these fittings were made by the local smiths in the villages where these houses were built, and from their frequency and variety in this part of England is evidence of a great power of design. In a window in the Kite's Nest, a farmhouse near Broadway, you will notice the ingenious way in which the one handle works the top and bottom catches, and how cleverly the initial S is worked in and dominates the entire design. Can we not fancy the pride and pleasure of the smith in making such a charming piece of work? The door furniture, hinges and lock plates show very great variety, and are evidences of a refinement of thought and feeling quite unknown amongst the rural population of the present day.

Plaster used in a constructional sense is uncommon, though there are a few instances in which the old "wattle and dab" treatment still remains. This is a rough framework of timber, covered with closely-woven and interlaced wicker-work, plastered on the outside face, the whole generally raised some four or five feet from the ground on a stone base. Only barns and farm buildings are treated in this way, and not the houses. In some instances the stone buildings have been stuccoed, probably about the latter end of last century, in a rather original way, leaving the mullioned windows and dressed stonework exposed and the flat wall spaces treated with stamped designs and decorations. Good examples are to be found in Stow-on-the-Wold and Burford, and other places.

The real timber and plaster house is never seen on the Cotswolds proper, but it is interesting to notice that directly one

gets into the Worcestershire and Warwickshire vale, where oak and chestnut abound, the timber treatment commences. At Broadway are some examples, though only fragmentary, and then used in connection with stone buildings and not as a separate structure.

At Todenham, some three or four miles from the Cotswolds, in the Warwickshire vale, is a very fine half-timbered house, &c.

What is the one great lesson to be derived from the study of this old work of the Cotswold district? It may be summed up in two words, "Simplicity" and "Restraint." The more you analyse and look into these old buildings the more you will discover that all their charm depends on the honest, simple and unaffected way in which they are treated.

If you take any of these houses and begin with the plan, you will notice how plain and direct is its purpose, and how suited to the lives and habits of the people who then occupied these houses. The rooms squarely treated, the windows and doors well placed, the fireplaces in the positions where most heat is obtainable (and yet where most effect is gained), all teach us a lesson that in our daily work we should do well to follow. The exterior, with its broad quiet wall surfaces and simple roof, with gables at either end of the building or with one gable standing out to mark the entrance, all tell of a breadth of treatment and a grasp of composition almost unknown to-day.

It must not be imagined that the great charm of these buildings is referable only to the softening and mellowing hand of time. Quiet grouping and dignified proportioning are great factors in their beauty of effect. Each building tells its own purpose at a glance—there is no mistaking the cottage for the manor-house, though one may contain as delicate and refined handiwork as the other. All are treated with a consummate skill and power that show a wonderful appreciation of the beautiful at this period.

I would urge you, in your studies of old buildings, to strive to analyse their composition. Do not merely sketch the quaint bits of striking detail, but try to discover for yourselves what it is that produces the effect you see before you. If you are studying the Cotswolds buildings you must assuredly come to the conclusion that everything depends on their quiet, refined and simple treatment. Try, I repeat, and find out for yourselves how such effects are produced, and study those effects and principles, even more than mere detail. The noblest buildings in all ages depend mainly on their proportions and treatment of surfaces, and I think you will agree that the nobler and simpler the proportions and the broader and quieter the surface, the grander in all respects the building.

Concentrate your grouping so as to give emphasis and point to parts of your design. Let some portions stand out distinctly, yet in harmony with the rest—your doorway, for instance, your dormers, roof or chimneys. Above all, let the enrichment and ornament be so placed that it has meaning and purpose.

Poor sculpture—in this instance I mean carved enrichment and so-called "ornament"—is the bane and curse of much modern work. How many buildings are absolutely ruined and their effect spoilt by being covered with bad carving laid on without object or purpose, in any position where there is wall space? We see many buildings that in themselves are good in their lines and grouping, yet with their proportions marred, their wall surface frittered away, by meaningless, commonplace carving. In the houses of all kinds in the Cotswold district carving is almost entirely absent, but when it is used in the building it tells its purpose, and has point and meaning, and justifies its own presence. In one group of buildings—the almshouses of Campden—a long line of quiet frontage, with a projecting gabled wing at either end raised on a terrace overlooking the road, there is but a single central panel—the arms of the founder surrounded by mantling and crest; and one instinctively turns to that simple carved stone with a feeling of admiration for the artist who designed these buildings, and the restraint he has exhibited in his work.

If you must have carving exercise your judgment and place it in positions where it will emphasise and help your design; do not put bands of carving round your chimneys or under your plinths, as we often see, and do not carve all your cornices and ornament.

There is one great feature about the work of these Cotswold builders—the certain way in which they obtained effect in their buildings. An enriched panel, a carved sun-dial, a coat-of-arms or a band of ornament are far more telling when rightly placed than a wealth of meaningless detail. Words fitly chosen, we are told, "are like apples of gold in a basket of silver." May we not say almost as much of wisely-chosen architectural details?

As a general rule I have always thought that if you design good mouldings with careful regard to their positions, and omit entirely all sculpture and carving, you will have a better building, and one that will live better in years to come than if you had depended on carving for effect.

Perhaps I go to an extreme, but to me bad carving is terrible. It is always an eyesore and an irritant. It is generally coarse and always vulgar—at the best dull and

insipid; but so many buildings are nowadays covered with this meaningless style of work—bodyless griffins swallowing their tales or corpulent cupids with wreaths of flowers—all true "fish out of water," having no regard or relation to the building and forming no part of its composition.

Aim at breadth and boldness in your designs, and cut out all the meaningless detail and detail that has no purpose to fulfil. Group your buildings so that all is harmonious, and look well to the principle of domination and subordination.

You may say that all this applies more to large buildings than to small everyday work, but there is as much design needed and breadth of treatment wanted for the cottage and small house as for the mansion. A speaker at a former meeting of the Association once said that he thought it a blessing that we had clients who put limitations to our work—and I think it a very true remark. If we had no difficulties to overcome, no conditions to fulfil, and no limit to our expenditure, we should soon be lost in a sea of architectural trouble.

It is the having strict conditions to adhere to, and a limit of cost to keep within, that not only gives zest to our work, but also restrains one's too exuberant fancies, and compels us to make the utmost of awkward sites and indifferent materials, though as a rule the more awkward the site, the more pleasure is obtainable in overcoming its difficulties.

Now let me say a few words about glass. Use all the clear white glass you possibly can, and if you must have any painted or stained windows, try and get the very best obtainable, both in colour and design, and worthy of the position it has to occupy. A simple shield and coat-of-arms, a single head or motto even on a riband, well painted and executed, attracts the eye at once. Standing out against the sky like a gleaming jewel, it is worth far more than many windows filled with interesting patterns of indifferent workmanship and material. In the country it is so far more interesting to see nature's handiwork than man's, that one does not care to be shut in by coloured glass when the sky and birds and flowers are to be seen. I know that opinions differ greatly as to large or small squares of glass, but for my part I would, wherever possible, break up the surface of windows into small panes, either with lead or wooden bars, so as to give scale and proportion to the building, and so avoid the bald, empty look of large sheets of plate-glass. Sometimes when these latter are used the rooms are often cold, and there seems to be a draught from the windows. The origin is in the room itself, and is created by the fire. The heated atmosphere of the room is lowered in temperature by impact against the large cold surface of the glass, and returns in the direction of the fire as a chilly draught. This will often account for rooms in which plate-glass has been substituted for the old lead lights being found so cold and draughty. Where the panes are small and the surface broken up, any tendency to this kind of draughtiness is not so noticeable. Of course in some positions plate-glass must be used. For example, where large and extensive views are wanted, and the small panes would destroy the prospects afforded. Still, as a general rule, a window treated as I suggest will be found best for both internal and external effect.

In towns and cities the use of coloured glass is allowable; here unsightly objects have often to be shut out, but in the country you cannot have too much clear glass. A great charm is added to a window by lead glazing in quiet patterns—not too intricate, so as to be fussy or irritating to the eye—but some of the varieties and simple contrasts obtainable by the use of squares and circles are always pleasing.

There are many villages and houses in the Cotswolds where the old glass remains intact, notably in Broadway and Campden, and the villages adjoining. This is generally tinted, from a pale amber tone to almost bottle green. It mostly was cast this colour, but a good deal is referable to age and exposure to the elements. In many of the houses—for the most part on the windows of the staircases—there are devices, crests, or initials painted in some few panes. In a charming early sixteenth-century house the glass in many of the lights has a bishop's mitre, or crozier, or other symbol; but most of this has been taken away, or broken up, and the house stripped of its panellings and furniture. It now, I believe, forms the residence of a ploughman. This fine old house was at one time the summer residence of the Bishops of Oxford, and belongs now to Christ Church College.

Endeavour to make your windows long and low so as to get all the light you can into your rooms—a long mullioned window of some six or eight lights is far pleasanter to sit by than a high window reaching nearly from floor to ceiling. At times a high sill with a wide window-seat is a charming feature in any room. And speaking of windows, I do not myself at all object, as so many do, to sash windows. These, in some instances, can be used with almost better effect than casements, and, if properly treated, always look well.

In country houses it is well to give great consideration to the plan, and your rooms should be well placed with a view to convenience inside, and also appearance outside. Remember that in the country a drawing-room is used nearly all day long,

and should have a southern aspect so as to get all the sun obtainable. It should command the garden, or part of it, and be sheltered from the approach to the house. Your hall should have a fireplace, and should be in a measure treated as a sitting-room, with the stairs close to and yet not opening directly out of it. It should be a bright, cheerful apartment, but with a greater air of dignity than the other rooms. The dining-room in a country house of any pretension should be ample in size—there is no greater mistake than to make a small dining-room in a country house—and the windows, in my opinion, should be placed rather high up above the ground, as this is more especially a room for meals, and will not be used much at other times, though in smaller houses where the dining-room is generally the living-room, it is more cheerful to keep the cill low. There should be a serving-door opening into a servery or lobby and not another room. A door is better than a hatch, which is useless without servants to work together, one on either side of it. At the best it forcibly recalls the city restaurant. The lavatories, &c., should be conveniently placed but yet quite apart, not on any account opening directly out of the hall, but out of a corridor leading to the billiard-room or the garden. It is most essential to provide a good lavatory on the ground-floor for the use of the male members of the family.

Fireplaces and chimneys will take all your time and ingenuity in country buildings, especially, as is so often the case, if your house is surrounded and overtopped by high trees. Without the very greatest care you will find some of them smoke, and all your labours will be thrown away and all your best endeavours nullified. Clients are obdurate where smoky chimneys are concerned, and the most beautiful chimneypiece, the most delightful ingle, is quite lost on them; and naturally, too, if they cannot get near them for smoke. One of the best arrangements is to build the flues with flat ledges, to take the down-draught and prevent the wind beating right down on the fire. Cows and pots are useless in many cases of smoky chimneys.

In conclusion, I would urge all the younger members of our profession to try and spend as much time on the works and in the workshops as possible. It is only there that we can see how our work develops, and note opportunities for improving it. You will find that your happiest hours are spent on your buildings, watching them grow from foundation to finish, and you will regret you cannot be there more.

Nothing is too small or beneath your notice if you would produce a successful building. Try all you can to do your duty, and sooner or later you will reap your reward. Oftentimes you will find the work on which you have spent most time and thought passes unnoticed; but you have the inner consciousness that it is done well, and that is its own true reward.

I would urge all students to try and get on some building from commencement to completion, either under some clerk of works or as one, and to learn thoroughly all the practical part of the profession. No amount of designing and drawing, however excellent, will make up for errors in construction and a want of practical knowledge.

Something has been said lately for and against a country practice. Having been articulated in the country, and seeing nothing but country work and ways all that time, I also can sing the praises of a country practice. You will doubtless all agree that we London architects know quite as much of the way our work goes on as if we lived in the midst of it. In these days, when our work is so scattered hundreds of miles apart, London, in my opinion, is the best centre for an architect, and I quite think we London architects are often as well acquainted with the country as those who live in it, and, if anything, more appreciative of the charming villages and beautiful rural scenes than those who live amongst them.

It must pain us all to see in so many villages the old-fashioned cottages and houses being swept away, and in their place hideous houses, rows in exact imitation one of another, vulgar and pretentious, bringing the artificiality of the town into the country. We hear so much nowadays of the country awakening to a great love of art, of the people appreciating architecture and wishing for a higher ideal in life and work and its surroundings, and yet year after year sees the rapid effacement of such villages as I have described to-night, not only in this particular district, but all over England. Everywhere there is a transformation to the commonplace and sordid, and the old houses and buildings are pulled down or so altered as to be unrecognisable.

There is an old proverb that bids us "take care of the pence and the pounds will take care of themselves." In respect to our old architecture we seem to go on an inverse principle.

We take care of the "pounds"—our great national buildings, our cathedrals, our churches and so on—and yet the poor little "pence," the cottages and small country houses that, in my opinion, are quite as characteristic, and as essentially marking an epoch in English architecture, we neglect altogether and are losing rapidly. Fortunately the Architectural Association does much to uphold the traditions of Old English Domestic

architecture. Its teaching all along has been directed to the cultivation of a love of that simple, homely style of building that finds its most perfect expression in our old country houses and villages such as those I have spoken of to-night.

Mr. R. W. PAUL proposed, and Mr. LEONARD STOKES seconded, a vote of thanks to Mr. Guy Dawber for his paper.

Mr. W. D. CARÖE, M.A., made allusion to the conjunction of Classic and Gothic styles in an old town not far from Wootton-under-Edge. He thought that plate-glass windows were more draughty than lead-light windows. Casement windows fastened up tighter than sashes filled with plate-glass.

Mr. F. R. FARROW said he hoped one result of the paper would be to induce the Association to make an excursion in the Cotswold district.

The PRESIDENT expressed his opinion that students gained more by studying small and simple buildings than by first of all going abroad to study cathedrals. The pictures shown were charming, and showed what beautiful effects could be got by simple means. When Queen Anne style arose he was told it was Low Dutch style. He went to Holland, but found it not. With some irony, the President added that he had not found in Holland the charming effects and features supposed to be seen in Bedford Park. He then put the vote, which was carried by acclamation.

Mr. GUY DAWBER acknowledged the compliment, and said that he believed the large expanse of plate-glass exercised a chilling effect. He did not agree with a previous speaker who spoke of a gentleman who had never properly realised the view from his window till he saw it through lead-lights. A wide and extensive landscape must be seen through plate-glass, and without dividing lines, for proper effect.

ST. PETER'S CHURCH, ST. ALBANS.

A SHORT account of St. Peter's Church, St. Albans, by Mr. F. W. Kinneir Tarte, appears in the current number of the *Hertfordshire Illustrated Review*. The author says:—

These notes on St. Peter's Church must necessarily be somewhat brief, and many interesting facts well worthy of attention must be passed over without comment. This is not surprising when we remember that the history of the site and of the present historical fabric carries us over a period of nearly one thousand years, during which time it has been rebuilt, altered and beautified. It has stood silently overlooking one of the most bloody strifes that Mediæval history records, and priests and kings, in their splendour and pomp, have passed in and out from its holy walls during the Middle Ages. History records that the founder, Wulsig (the sixth abbot), was a man of piety and well-ordered life, who shone conspicuously both in spiritual and secular matters. He encouraged people to come and settle in the town, finding them material and money. In the reign of Edred (about 948), he built churches at the entrances to the town—at the north, St. Peter's; south, St. Stephen's; and west, St. Michael's—each of them on one of the three principal roads leading to his monastery.

I can find no further notes until the time of Geoffrey de Gorham, sixteenth abbot (1119-46), who bestowed the sacred edifice, with all its belongings, to the perpetual use of the infirmary of the monastery, all matters relating to the church being controlled by the priest (infirmarer), in order to provide food and medicine. Abbot Warren (1183-95) assigned the altar offerings for the medicine of the sick in the infirmary, so that it appears likely that the former had been otherwise applied in the interval. In 1253 these were given to the vicar of St. Peter's on the ordination of the vicarage by the Bishop of Lincoln.

The advowson of the vicarage continued in the abbot and convent of St. Albans till their dissolution, upon which it came to the Crown, and was given by King Edward VI., in the first year of his reign, to the College of Fotheringay, in Northamptonshire. But that house being soon after dissolved, it was again devolved upon the Crown, in which the patronage of the vicarage continued until it came into possession of Thomas, Lord Seymour, of Sudley, and, upon his attainder, reverted to the Crown, and was granted, on June 17, 1600, by Queen Elizabeth, to Martin Heton, Bishop of Ely, and his successors; for it appears that King Charles I. presented to it in 1637 by reason of the vacancy of the bishopric of Ely, and after the restoration of Charles II. the bishop again presented to it.

Godfrey, Bishop of St. Asaph, consecrated an altar in honour of St. Nicholas in the time of Abbot Robert de Gorham, and on December 26, 1215, at the request of Abbot William Trumpington, Thomas, Bishop of Durham, dedicated the cemetery. This, it will be noted, was in the year after the removal of the interdict. Probably this was an enlargement, for burials had taken place in churchyards since about 758. Large numbers of persons were buried in the churchyard in 1247, when a pestilence swept over the town.

In the early part of the thirteenth century the church may

possibly have been rebuilt. The only portion, however, of this date that still remains is the west doorway. This entrance is in the centre of the present west elevation, the whole of the other portions of the elevation being of a later date. It is perhaps desirable to mention here that, so far as I can trace, no vestiges remain of the original church built by Abbot Wulsig.

A great calamity occurred on the vigil of the Assumption of the Blessed Virgin Mary in 1254, for during a thunderstorm the tower was struck by lightning, the oak timber-work at the top being shivered and destroyed; and it is further related that an intolerable stench and smoke was left in the tower and church. Building was evidently going on between the years 1335-49, for the parishioners cut down certain trees in the churchyard which were valued at twenty-five shillings, for the use of the work at the church. These people were promptly excommunicated by sentence of the archdeacon, for doing this without the license of the rector, but, fortunately for them, pardon was granted on being submissively asked for. A similar irregularity took place in the time of Abbot Thomas de la Mare (1349-96) and was again repressed.

It was part of the duty of the vicar of St. Peter's to provide one horse for Abbot Richard Walyngforde when he travelled to visit the cell of Tynemouth. A carved cross was erected in 1342 in the churchyard by Master Roger de Stoke, a clock-maker, which he had executed himself on successive Fridays while fasting. It apparently gained considerable notoriety from the fact that miracles were worked at it, and consequently it became the means of drawing offerings. William Puffe was vicar at this time, and he was judged by the Consistory Court to pay a fine of forty shillings to the infirmarer for having appropriated these oblations. It is unfortunate that during the rebellion, headed by Wat Tyler, 1380, the books of the vicar and the Grange of St. Peter's were burnt by the rioters. Richard II., attended by Judge Tresilian and one thousand soldiers, visited the town to try the delinquents, and many of the townsmen were executed.

Though very fragmentary, those who visit the church should not miss seeing the coloured glass in the windows of the north aisle. Gough, writing at the beginning of the century, states that "much of the painted glass was broken by thrusting the scaffold poles through the windows." At the present time the glass is very much "mixed up." The Rev. H. Fowler says:—"Two of the pictures appear to illustrate the life of the patron saint of the church. In the second window from the west is represented the incident of St. Peter striking off the ear of Malchus in the Garden of Gethsemane; the retreating figure on the left is probably Malchus. Our Lord stands near, having His hands bound before Him. The picture in the most eastern window, in the cusped head of the light, is a small figure of an ecclesiastic holding in his left hand a model of a church; his right hand is raised in an attitude of benediction. This no doubt represents the Saxon abbot, Ulsinus, the founder of the church. The subject in the second window from the east is St. Peter preaching to Cornelius. In the head of the light of the window St. Peter is depicted seated on a throne, holding in his right hand a key, in his left a book. St. Lawrence, with his gridiron, appears in one of the small compartments of the tracery." In the second window from the east are the arms of Edmund de Langley, fifth son of Edward III., who died 1402, and whose fine tomb still exists in the chapel of King's Langley church.

Several of the subjects have a horseshoe border, and from this significant fact Mr. Fowler suggests that the donor of the glass was probably a person named Ferrers, some members of whose family resided in St. Albans about 1400, their badge being a horseshoe. A shield of arms on the ceiling of the north transept of the abbey, "Ar., 6 horseshoes Sa.," was assigned to the Ferrers by Clutterbuck. Many payments are recorded in the churchwardens' accounts for repairs to church windows. It is surprising that any glass of this period remains when we find in these accounts that the Colchester prisoners were confined there in 1649, and an item charged for taking down the windows and removing things out of the church. In 1644-45 a man came and obliterated the "Popish sentiments" that were on graves and on windows, for which he was paid five shillings. An interesting note in "Elizabethan England" states "that all images, shrines, tabernacles, rood-lofts and monuments of idolatry are removed, taken down and defaced, only the storeys in glass windows excepted, which for want of sufficient store of new stuff and by reason of extreme charge that should grow by the alteration of the same into white panes throughout the realm are not altogether abolished in most places at once, but by little and little suffered to decay, that white glass may be provided and set up in their rooms."

A guild, consisting of persons of the upper class, under the invocation of St. John the Baptist, held their meetings in St. Peter's Church during the fifteenth century. In a certificate of chantries it is recorded that "The Fraternite, a guild called the Brotherhood of All Saints, is founded in the Charnell Chapel, which chapel is builded within the churchyard of St. Peters."

This is, without doubt, the chapel of the Holy Cross, which stood in the cemetery of St. Peter's Church in the reign of Henry IV. (1399-1413), and which Mr. A. E. Gibbs points out as existing in the year 1634.

More than one anchoress has taken up her abode at St. Peter's Church, for we read that, in the year 1258, an anchoress had a parlour at the church, in which she saw the vision of an aged man, who ascended to the top of the tower, and cried, "Woe to the inhabitants of the land." In this year a great famine occurred, when 16,000 persons died in London. During the stay of King Henry VI. at the abbey, in 1458, His Majesty visited the cell of the anchoress of St. Peter's. In 1479 Elizabeth Katerina Holsted, a widow, was the anchoress. She was consecrated by Abbot William Walyngforde; this was an occasion of great solemnity, the abbot celebrating mass.

On the feast of St. Vitalis, 1427, a synod of clergy was held in the church for the repression of the Lollard doctrines. Three persons were named for the offence of holding heretical opinions, and for possessing books written in the vulgar tongue. Two appear to have been able to clear themselves, but William Redhead, a maltman of Barnet, confessed he had such a book and that he often read it. His penance was rather severe, for he was to offer a wax candle of the weight of a pound in honour of St. Alban. On three Sundays immediately succeeding he was to walk, divested of his garments, around the cemetery of his parish church in front of the procession; after his return to church he should go to the high altar and there offer, on bended knees, the wax candle which he carried in his hand; and as a final remission of the offence, he was to walk with upraised hands through the public street to the Cross, and there burn that execrable book which before he had joyously read.

On May 21-22, 1455, the first battle of St. Albans took place, and among those who fought on the Lancastrian side and afterwards died of his wounds, was Sir Bertram Entwistle, Knight, who (Leland affirms) was buried under the place of the lectorium in the choir. Chauncy in mentioning the incident gives the inscription, which was evidently engraved on brass. Another account (1824) says that "the memorial was a brass figure of a knight in armour, a fragment of which was preserved in the late vestry. The form of the handle of the sword which the knight is represented as wearing is exactly similar to that of a real sword, said to have belonged to Sir Bertin Entwysel, found in digging up the foundations of the chancel during the last repairs. Gough, writing in the early part of this century, says that the brass has disappeared."

The second battle of St. Albans was fought on February 17, 1461—

Upon a Shrove-Tuesday, on a green leed,
Betwix Sandridge and Saint Albans many man 'gan bleed.

Special attention is drawn to these battles because a number of the slain were interred in the church and churchyard. Not many years since a helm and anklets were dug up in the churchyard and are now preserved in the vestry; these, in all probability, were buried with the warrior after one of the battles.

The church possessed a number of brasses at the end of last century. The building still contains several monuments, of which the most interesting, perhaps, is that fixed on the east wall of the north transept, commemorating, in flattering terms, the virtues of Edward Strong, master mason of St. Paul's Cathedral, who died in 1723. This famous mason, be it remembered, was a resident in St. Albans, and probably built several houses in the city.

The nave is divided from the north and south transepts by a series of arches, six on each side; these, together with the aisle windows, belong to the fifteenth century. The columns of the nave arches are lofty and well-proportioned, while the general effect of the interior of the church is striking and picturesque. From time to time it has been decorated, several items appearing in the churchwardens' accounts for writing up sentences of scripture, setting up the king's arms, decorating and gilding the pulpit, &c. In 1657 there is an item for clock and chimes. Thirteen years later the church was reported by the churchwardens to be in a bad state of repair, the sum of 80*l.* being necessary to restore it. Mr. A. E. Gibbs has recently published some interesting notes on the church, which have been collected from the churchwardens' accounts and vestry orders from the year 1573, and he has kindly placed his original extracts at my disposal. From these I gather that constructional repairs were being carried out in the tower in 1785-86, large sums of money being raised for this purpose.

The work to the tower appears to have been most unsatisfactory. On July 11, 1799, the bells and frame were to be removed, and the tower was to be taken down as far as the tops of the arches, and on October 21 following "the opening caused by this demolition was to be roofed over." All the vestry orders dating between April 1802 and November 1806 have mysteriously disappeared, so that no information can be obtained from this source. From the account of the repairs and alterations to the church given in the "Beauties of England and Wales," we learn that "the close of the scene

was on Saturday morning, November 21, 1801; the whole floor of the belfry fell at once into the body of the church." It is said that the sum of 2,790*l.* was wasted in these repairs. An Act was applied for and passed in 1803, and the Bishop of Ely, to whom the chancel belonged, agreed to its being made smaller. From the above accounts it seems that the tower was partially taken down in 1799, and that the present tower was commenced in November 1802. Clutterbuck says the work was completed in 1806.

It was during these alterations that the chancel was shortened some 30 feet, and the transepts taken down. The material of which the church is built externally varies considerably, the nave being faced with flints, local rubble and local stone dressings. The tower is of brick, and the east front of the chancel, the vestry and the porch, are of stone. With the exception of those portions constructed of stone, the whole of the church has been covered with "rough cast," of which Gough remarks, "The whole outside was plastered over by a London workman (a prevailing fashion of destroying the effect and beauty of our best parish churches), and though done three or four times over, the plaster is now flaking off, both within and without." At the present time the church presents a very dilapidated appearance, and probably was never in greater need of repair. It has been patched with pieces of tile and bricks, and the stone window tracery has been filled in with cement to an alarming extent. The progress of neglect has rarely been more fully exemplified than it is in the church of St. Peter's. However, owing to the generosity of Lord Grimthorpe, the sacred edifice is likely to receive a new lease of life, and all parishioners should be grateful to his lordship for having removed a great responsibility from their shoulders.

It will be seen that the nave of the present church differs little from the south view taken by Baskerville in 1787. It is here represented as having a tower and short spire, the tower having a staircase at the north-east angle, the top of which can just be observed in the sketch. The chancel had a doorway at the west side of the projecting building, which Salmon describes as being a chapel or vestry. In the interior of the chancel, on either side, was a row of carved-oak stalls.

The organ is in a gallery at the west end of the nave. It was the gift of Christopher Pache, M.D., and was opened in 1725-26. In 1731-32 considerable additions were made to the instrument.

GOODRICH CASTLE.

THE origin of Goodrich Castle seems to be involved in some obscurity. Castellum Godrici, its ancient appellation, demonstrates that it owes its foundation to some one of the name of Godric. Grose considers that Godricus Dux, whose name twice occurs as a witness of charters of Canute, was the founder; but this opinion has not always been received, as the monasteries to which those charters have relation were at Hulme, in Norfolk, and St. Edmundsbury, in Suffolk. The incursions, however, by the Welsh into the Marches or English borders had been so successful as to encourage their boldness, and which would afford some reason for the erection of a fortress in this situation. In 1057 Leofric, Earl of Leicester, having died, he was succeeded by his son Algar, who was soon afterwards removed to make room for Ranulph Meschines, Earl of Chester. This being resented by Algar, he entered into a league with Gryffydd ab Cynan, Prince of North Wales, when, uniting their forces, they made a powerful irruption, and ravaged the Marches. They defeated Ranulph within two miles of Hereford, and having destroyed the city, returned to Wales in triumph in the year 1058.

Edward the Confessor raised Harold, second son of the Earl of Kent, to the earldom of Hereford, and sent him in 1059 with considerable force to retaliate the injuries inflicted by the Welsh. Advancing upon their hills, Harold laid everything waste. A law was enacted that every Briton from that time after who should be found with a weapon on this side of the limit he had prescribed, namely, Offa's Dyke, should have his right hand cut off by the officers of the king.

On his return from this expedition Harold rebuilt and fortified the city of Hereford. This, however, did not retard the Welsh from renewing their provocations; for Gryffydd ab Cynan and Algar having retreated into South Wales, the latter engaged Gryffydd ab Llewelyn to espouse his cause. In 1063 Harold again took the field; and, being successful in North Wales, marched in the next year into South Wales, where Gryffydd ab Llewelyn was vanquished and slain. The inhabitants of Wales submitted to pay tribute; and on this occasion a castle was first built to guard the Willow or Wel across the Wye, by some important person, from whom it was called Godric's Castle. It is not mentioned in Domesday, though five individuals named Godric occur as holding lands in other parts of the county of Hereford.

In the Liber Niger Scaccarii, however, we are informed that in the reign of Henry II. William Marshal, Earl of Pem-

broke, held of the abbey of Winchcombe, in Gloucestershire, *inter alia*, sixty-five knights' fees and a half in the honour of Striguil, and two knights' fees with the castle of Goodrich, and on reference to Dugdale we find that, in 811, Kenulph, king of Mercia, amply endowed that abbey, and that from 1054, till after the Norman Conquest, Godric was its abbot. Thus some light is thrown upon the early history of the castle, which also affords a conjecture as to the probability that Godric, the abbot, was the first who erected it.

There appears to be no record extant of the first governors of this fortress, but traditionally it seems to have been held by the Clares, as in 1135 Richard de Clare, Earl of Hereford, is supposed to have held it from the circumstance of having proceeded on a journey from Netherwent into Cardiganshire (Goodrich Castle being situated in the Netherwent or Gwentys-coed), when he was slain on his way in a private feud by Morgan ab Owain, with his son Gilbert de Clare, in 1136.

There is an architectural description of Goodrich Castle in King's "Munimenta Antiqua"; and in the Harl. MS., No. 6,726, fo. 54, sub "Gotheridge," will also be found several interesting notices, compiled by Silas Taylor in 1655, who gives an account of its then appearance. He says:—"About a quarter of a mile or thereabouts from the church is the Castle of Goodrich, a very strong pile, a mighty deep trench being hewn in the maine rock, where it wants the steepnes of the hill w^{ch} it hath upon 2 sides and part of the 3rd. The entrance into it, through a strong gatehouse, is over a little neck of land borne up on both sides with stone work, and is towards the east. It is noe great circuit. It is almost square in figure, having 4 great round towers for its defence at the 4 corners of it. When you are passed the strong gate of the castle, the first thing on your left hand is a chapple, wth the picture of a talbot on the south wall, with the garter of St. George about it, and an earles crownett upon it. It is reported that the keepe of the castle was by way of ransome built by one Macbeth or Macmac, an Irish comander, who with his sonne was taken prisoner by John Earle of Shrewsbury in Ireland, and here imprisoned, and to this day it is called Macbeth's Tower, and to our times were alsoe kept in this castle the memorialls of this atchievement, viz. the two head-pieces of father and sonne, of that vastness and capacity that the one would hold half a bushell of graine; the less was very thicke, and both very ponderous. The lady's tower was battered by Coll. Birch. It is reported by many witnesses that y^e cellars of the castle were floored with Irish earth, for that whenever they brought a toade into them and laide it on y^e earth it would dye, and this they did to preserve their cellars from venome, and it is thought that the very timber came alsoe from Ireland, for there was not either spider or cobwebbe to be seen, but it is reported that in Monmouthshire there is a little spott of land of that nature. The hall was on the west side of the castle, where was observable a beame of oake intire without knott or knarle of 66 feet long, and held 20 inches of 2 feet square the whole length. The hall itself was 60 feet, allowing 3 feet for the beame in the wall."

The keep-tower, which is a Norman structure, is formed of stone from the Forest of Dean, and of excellent masonry. It was called Macbeth's Tower in connection with the tradition above mentioned; but which has been interpreted to relate to the circumstance of Strongbow, who held the castle, capturing Waterford in Ireland, and taking Reginald the Danish chief and O'Falan the Irish king of the Decies, whose lives were spared to strengthen his interest in that country.

To the year 1172, when Strongbow returned from Ireland to propitiate Henry III., we may attribute the period of the commencement of the present keep, the previous structure having been no doubt simply of wood, and perhaps surrounded by a wall. This tower was a place of great strength, and a fit occasional residence for its possessor, partaking of the general character of border castles. John Talbot, first Earl of Shrewsbury, is supposed, in the time of Henry VI., to have inserted two windows in the keep-tower; also two in the chapel, of which till within a few years ago some portions of the tracery remained, though now completely gone. Walter Marshal, Earl of Pembroke, died in the upper chamber of the keep in 1246. William de Valence, Earl of Pembroke (*jure uxoris*), who married his niece, Joan, daughter of Warine de Montchensi and Joan one of the sisters and coheirs of Walter, died in 1296, to whom, from his love of splendour, as well as to his riches, have been ascribed the round towers, curtains, and rooms now in ruins. The style in which they were built corresponds with the age in which William de Valence flourished; but whether those extensive buildings were not in reality erected by his widow, who died seized of the castle in 1307, or by Aylmer de Valence, Earl of Pembroke, their son, there may be some occasion to surmise. An immense moat was excavated from the rock which furnished stones for the purpose, and contributed to construct such a fortress with every contrivance to render it impregnable in the then system of warfare, the remains of which exist at this time in a sufficient degree to attest its former strength and magnificence.

The possession of the castle ultimately came to the Talbots,

Earls of Shrewsbury. Sir Richard Talbot, Lord Talbot, having married Elizabeth, the daughter of John Comyn, one of the competitors for the crown of Scotland, and Joan, his wife, sister and co-heir of Aylmer de Valence, became the possessor of Goodrich Castle, *jure uxoris*; and though he does not appear to have repaired the castle, he did much towards the embellishment of Goodrich Church, and obtained from Edward III. the grant of a prison in Goodrich Castle for the punishment of malefactors.

In 15 Ric. II., Richard Lord Talbot, grandson of Sir Richard Talbot just mentioned, was found to be one of the cousins and heirs to John, the son of John de Hastings, Earl of Pembroke, viz. the son of Sir Gilbert Talbot, K.G., son of Elizabeth, daughter of Joan, one of the sisters and heirs of Aylmer de Valence, Earl of Pembroke, and therefore succeeded to his possessions.

We are now arrived at the period when the sculptures on the walls are supposed to have been made, probably by some unhappy persons who were imprisoned in the south-east tower of this fortress in the latter part of the fourteenth century. These sculptures are made in the stone walls of the apartment in the first floor of the tower, on the sides of the east and west windows, the figures composing them being formed by cutting away the surrounding stone, and leaving them as in a sort of alto-relievo.

The first, cut upon the south side of the west window, reads thus, MASTR SUM ADAM HASTYNS. It is accompanied by a figure of a man, apparently crowned, with a divided beard; and, according to the opinion of Sir Samuel Meyrick, in the costume of the time of Richard II. He is holding a hawk on his hand, and below him is a dog.

The remaining sculptures are in the east window. One represents a similar figure of a man to that just described, in the same costume, with a divided beard, and wearing a coronet distinctly composed of what are termed in modern heraldry strawberry leaves. He holds a hawk upon his hand. This figure is not so high in relief as the others, and is little more than an outline. The remaining figures consist of the Virgin (crowned) and child; a stag couchant and swan; a hawk, belled, pouncing on a bird; a hare and rabbit; and a bird, apparently a pheasant.

The figures of the animals are evidently drawn by a hand not unacquainted with the nature of animals, as upon inspection they will be found to possess some good drawing, considering the period of their execution. It has been suggested that the stag and the swan represent the badges of Richard II. and Henry IV. respectively; but there does not seem to be sufficient evidence of this, or that it was the intention of the artist that they should be considered so, because all the animals above enumerated are associated with the wild sports of the day.

Goodrich Castle remained in the Talbot family till towards the end of the reign of Queen Elizabeth, when George, sixth Earl of Shrewsbury, marrying Elizabeth, the daughter and heir of John Hardwick, of Hardwick, in the county of Derby (and widow successively of Robert Barlow, of Barlow, in that county Sir William Cavendish, Treasurer of the Chamber to Henry VIII., and of William St. Lo, knight, Captain of the Guard to Queen Elizabeth), obtained a license to alienate the castle of Goodrich, and other estates, in favour of her son, Henry Cavendish, who married Grace, a daughter of the earl by his former wife.

George, sixth Earl of Shrewsbury, was succeeded in 1590 by his son Gilbert, the seventh earl. Gilbert married Mary, daughter of the before-mentioned Sir William Cavendish, and Elizabeth, afterwards Countess of Shrewsbury, but died in 1616, leaving three daughters his co-heirs, of whom Elizabeth became the wife of Henry Grey, Earl of Kent, to whom she brought the Goodrich Castle estate. This lady survived her husband, who died without issue in 1639, and retained possession of the castle during her life.

It was during the period of the Countess of Kent's possession that this ancient fabric at length fell from its former and wonted magnificence in the disastrous civil wars of the seventeenth century, having sustained a siege by the Parliamentarians in 1646, when, after a stout resistance, it surrendered to Colonel Birch on July 31 in that year. In the March following the Parliament ordered it to be demolished; and, as far as its former capacity for defence was concerned, the order of Parliament was effectually executed. The Countess of Kent did not long survive the destruction of her property. She died in 1651.

In her will dated June 20, 1649, she confirms a settlement of her estates which she had made in the previous year, and by which she had conveyed the Goodrich property to her own use for life, with remainder to the heirs of her body, ultimate remainder being to such persons who were named in the settlement. On her decease it devolved upon Anthony Grey, eleventh Earl of Kent, who was lineally descended from George Grey, second Earl of Kent, the great-great-grandfather of her husband.

Anthony, Earl of Kent, died in 1702, and was then suc-

ceeded by his son, Henry, the twelfth earl, who was created Marquess of Kent, Earl of Harold and Viscount Goodrich, and subsequently Duke of Kent. He was sometime Lord Chamberlain to Queen Anne, by whom these honours were conferred. On his death, without issue male, in 1740, his estates, pursuant to an Act of Parliament passed in 1725, were sold. Goodrich Castle was purchased by Admiral Griffin.

THE DERBY COLLECTION OF MINERALS.

ACCORDING to Mr. Bryce Wright, who formed the collections (now left to the Liverpool Museum) in their entirety for the late Earl of Derby, during a period of twenty years, the minerals are of much interest. The antiquities are already in the possession of the Liverpool authorities, they having been presented to the city in 1890. The collection of minerals represents principally one great division of mineralogy, that of silica, in its varied forms of quartz, rock, crystal, agate, chalcedony, jasper, &c., with a series of earthy and metalliferous minerals, such as labradorites, precious opals, malachites, rhodonites, &c., used for economic and decorative purposes. Few, indeed, have been the collectors of cut and polished agates during the last half century, but it is interesting to note that the collectors of such specimens have all been eminently men of the highest culture and attainments. To the ordinary mind one agate is the same as another—a centre generally of black, brown or white silica, surrounded by concentric parallel zones of chalcedony—but to the serious collector or connoisseur the deposition of each stratum tells a distinct tale of nature's work, whilst the thinning or thickening of the strata or the intrusion of a foreign substance gives rise to serious hypotheses. The agates brought from India by Dr. Birdwood were perhaps the first series during the last fifty years to attract particular attention. Then followed the commencement of the great collection by Professor John Ruskin, simultaneously with a very fine series made by the great omnivorous collector, Mr. Alfred Morrison, whose generous and liberal mode of collecting at the time gave a great impetus to the searching for such specimens in Europe. Professor Ruskin's papers and articles in the *Geological Magazine* and elsewhere upon the formation of agates, some fifteen or twenty years before his catalogue of specimens of "native silica" and arrangement of the series of specimens now in the British Museum, started a few earnest collectors, one the late Mr. Arthur Wells, of Nottingham, better known as the great collector of jade, who formed a small but extremely fine series with great care. The writings of Professor Ruskin were perhaps also the cause of the commencement of Lord Derby's collection, which for beauty, rarity and size may fairly claim to be at the present day unsurpassed. Purchasing single specimens at first for their beauty, these accumulated so rapidly that a cabinet was decided upon to hold them; then the collecting began in earnest, and for the last twelve years not a single specimen of sufficient merit has appeared in London which has not found a place in the cabinet. Any specimen which particularly struck Lord Derby was procured if possible in duplicate, so that there are four, five and even more sections of many important examples in the collection. Thus there are no less than four rectangular slabs of transparent green moss agates, measuring 13 inches by 8 inches each, and half an inch thick, as well as dozens of others of different sizes and shapes. The onyx-agates, chalcedonies and fortification agates can be counted by the hundred, whilst the same may be said of the jaspers, which are seen in every conceivable colour and shape, from the beautiful striped or ribbon jaspers—the deep green and crimson spotted heliotrope of India—to the brown conoidic forms of the Egyptian pebbles. The deep and bright browns and reds from Siberia, Germany, Scotland and many parts of South America are all plentifully represented, beautifully cut, mostly polished on both sides. Dozens of specimens of sard, sardonyx, cornelians, plasma, prase, &c., are met with, all exhibiting their individual characteristics of deposition, formation and colour. Circular agates formed by fine concentric strata of chalcedony and onyx surrounded by translucent crypto-crystalline silica or quartz, often with an opaline tinge, Lord Derby was specially anxious to procure, so that a large series of these, the most beautiful perhaps of all sections, are in the collection. One slab (a duplicate of which is in Professor Ruskin's collection) is perfection. A distinct circle about 3 inches in diameter, composed of extremely minute grey, blue and white concentric strata, is surrounded by a border of transparent filiform and crypto-crystalline silica, in which the rhombohedral form with planes of the apices of the crystals are distinctly discernible. Silicified corals, many of them evidently changed from carbonate of lime, but still distinctly retaining their primitive structure and exhibiting the septæ, are well represented, as are also the milk and blue-white Mocha stones, with their lovely dendritic markings of manganese and other metallic substances, so tree-like in appearance that one can be

forgiven for thinking they are of vegetable origin. One section of an abnormal agate must not be forgotten; it is a long oval specimen, measuring $1\frac{1}{2}$ inches by $\frac{7}{8}$ inches wide, of beautiful amorphous silica and agate, but only the eighth of an inch in thickness. Polished beautifully on both sides, it is quite transparent, but every minute stratum or zone, although some are only the many thousandth part of an inch in thickness, can be clearly defined.

As recently as the commencement of this year Lord Derby added to the collection a series of most beautiful transparent polished specimens of rock crystals enclosing acicular crystals of rutile, the oxide of titanium, the "Flèches d'Amour" or "Love's darts" of the French, also called "Venus Hair." One specimen is quite unique, large bunches of resplendent golden needle-like crystals crossing indiscriminately under the pellucid quartz. Passing from the silicas, which form the principal part of the collection, there is a large series of slabs of other important minerals, both earthy and metalliferous. In the former may be mentioned lovely chatoyant labradorites, brilliant in every conceivable prismatic hue; microclines, blazing in their metallic blue moonlight tints; lumachelle or fire marbles, glistening in their shelly matrix; aventurines (green and red), sparkling brilliantly; sections of lovely transparent fluor spars, in such exquisite tints of purple, blue, red and orange as to defy description; precious opal slabs, gleaming with their myriad harlequin reflections of every colour; as well as thulites, dichroites and many species and varieties too numerous to mention here. Of the metallic specimens, there are beautiful examples of the emerald green carbonate of copper malachite, showing its botryoidal and reniform structure as well as its aqueous formation; rhodonite, the rose-red manganese; chrysocolla, the silicate of copper associated with azurite, the blue carbonate, and many other metallic rarities. A small series of interesting and very valuable meteors, representing the three classes—siderites, litholites and lithosiderites—must not be omitted, as well as a drawer consisting of balls cut from agates, jaspers, thulites and other minerals, one being cut from a large star carbuncle showing clearly the asteroid of four lines. The whole cabinet contains seven hundred specimens, and the Liverpool Museum can fairly claim to be in the possession of the finest collection of its kind in existence. It is pre-eminently a collection of beautiful specimens, and when they are properly and scientifically arranged, as they doubtless will be, attention being paid to the disposition of light—many specimens requiring the transmission of light through them—they will present a spectacle that cannot fail to arrest the attention of even the most unobservant; whilst the student will learn once again through a new channel of the marvellous and glorious beauty revealed through nature. Although Lord Derby always disclaimed any scientific knowledge of the specimens forming his collection, he was quite *au fait* with the writings of Professor John Ruskin and Professor F. W. Rudler, of the Museum of Practical Geology, as well as of the theories and hypotheses advanced upon the formation of agates by Professor Heddle, Herren G. Lange and Bischoff, as well as Professor V. Ball and others.

ARCHITECTURAL ASSOCIATION STUDENTS' SMOKING CONCERT.

THE annual smoking concert of the Architectural Association students was held at the Mona Hotel, Covent Garden, on Monday evening last, when the president, Mr. H. O. Creswell, presided. There was a large muster of members present, and the Chairman was supported by Messrs. Goldsmith, Farrow, Baggallay, Earle, Elsey-Smith, Lewis, Max Clarke and Cole Adams. Messrs. E. Graham Simpson, S. B. Lee and E. O. Cummins efficiently discharged the secretarial duties.

The Future of Architecture.

SIR,—I have twice recently almost suffered an attack of syncope on reading the architectural matter in my daily paper. Amidst much laughter in the course of a discussion in the House of Commons on May 5, on the vote of 11,200*l.* for the Admiralty buildings, the Secretary of State said that the architecture of the design first proposed was in "the debased provincial municipal buildings style; but that the Select Committee came to the conclusion that a far better style of architecture would be found in the existing Admiralty buildings, the architect of which (Sir Christopher Wren) was content with simplicity and proportion. He was afraid that every public building was more inconvenient than its predecessor, for the

Foreign Office block had been surpassed by the Royal Courts of Justice of Mr. Street." Yet, sir, this last architect is buried in Westminster Abbey, and, like the former, has his monument in a conspicuous place on his last and most important work. It is strange that on a subject involving as much science as taste there should be such diversity of opinion. Then I read that at a conference in Liverpool recently Mr. Arthur Cates, a very active member of the Council of the Royal Institute of British Architects, London, obtained the support of about a dozen delegates and local architects to the following proposition, viz., "For dividing the United Kingdom into architectural provinces or districts, of which the societies now or hereafter to be allied to the Royal Institute would be the respective centres, one object being . . . the promotion, amongst other things, of architectural education." This looks rather like architecture in bonds and tears. As an old practitioner fairly well satisfied with his past success, I wish every possible advantage may accrue to my brethren from this movement, though from the standpoint of the past it is a most extraordinary one, and though I doubt whether the principles of the martinet and the action of the drill-sergeant will succeed in conferring the present much-needed vitality on British national architecture, which is the object in view. Perhaps if the R.I.B.A. appoints a popular architectural lecturer in each province improvement may ensue in time. But I fear that the members of the Council of the Institute think more of personal advantage and the promotion of selfish interests than of the vitality or improvement of architecture. The R.I.B.A. is emphatically for architects first, and only secondly, if it may be, for architecture, the first of arts. If this be true, the sooner we have a college of architecture the better; the present club would doubtless still have sufficient *raison d'être* for continued existence. You allowed me to say a few words in favour of this theory in your issue of June 22, 1888. The reply, as far as I could gather, was that the R.I.B.A. was already a college, a claim I must deny emphatically, for I think it is just the characteristic wanting in the Charter of the Institute, which does not represent the large majority of architects. I conclude with the following words from that communication:—"Professors, critics and men actually engaged in the art confess and urge that it is in an unsatisfactory position at the present day. Mr. Herbert Spencer tells us that of all the arts architecture is the only one that has not been far surpassed by the moderns, except only statuary, and that as architects persist in copying the work of other men and other times society has no respect for their productions, and they consequently do not take rank as they would do if their art could be placed upon a better footing." Here then, surely, is a business worthy of our most distinguished and eminent men, in or outside the R.I.B.A., and accepting the above words as undeniably sound in argument, it should be undertaken without delay. HERMES.

GENERAL.

A Number of Students from the plumbing classes connected with the Goldsmiths' Institute and the Croydon Polytechnic visited the Museum of Sanitary Appliances at Highgate on Saturday last, the 13th inst. They were met by Mr. Thomas de Courcy Meade, M.Inst.C.E., the engineer and surveyor to the Hornsey Local Board, and Mr. Taylor, R.P., one of the gentlemen engaged in giving lectures on plumbing at the Museum, in connection with the Technical Education Committee of the Middlesex County Council. After spending some three hours there in examining the exhibits the students left, expressing their appreciation of the completeness of the Museum and the excellence of the exhibits.

The Architectural Association Lyric Club Committee announce that the last concert of the fifth session will be held at the Freemasons' Tavern on Monday, the 29th inst., at 7.30. The nomination of officers for the ensuing season will also take place.

Mr. Percy E. Newberry has brought back from Upper Egypt several drawings of ancient tombs in the province of Minieh and Assiout, which were prepared by Messrs. Percy Buckman, J. E. Newbury and Howard Carter, in connection with the archaeological survey of Upper Egypt. Next month there will be an exhibition of the drawings.

The New Church at Turner's Hill, Sussex, for which Mr. Lacy W. Ridge's plans have been selected, will shortly be commenced. The nave and aisle will cost 2,300*l.*; chancel, organ chamber and vestries, 1,200*l.*; tower and porches, 2,000*l.*

Bishop's Court, the residence of the Bishop of Sodor and Man, was partly destroyed by fire on Monday. The valuable documents belonging to the see were consumed, but the pictures were saved.

The Exhibition of the Royal Scottish Academy, which was opened in February, closed on Saturday, the 13th inst., after a successful season, the attendance having, it is stated, exceeded that of any previous year.

The Architect.

THE WEEK.

THE magistrate at Greenwich has given a decision which it is to be hoped will be taken as a precedent. The case was not altogether novel. It was a maxim of ADAM SMITH that "the tax which each individual is bound to pay ought to be certain, and not arbitrary." But of late years local and other authorities prefer to imitate the Scottish lairds, who impose a fine on every tourist who lands from a steamer, although his stay on land may be counted by minutes. Consequently, Messrs. PEARSON & SON, who are making the Blackwall Tunnel, were probably not surprised when rates were demanded from them for having set up plant on the Greenwich marshes. Every contractor of standing has had experience of demands which, practically, are of the same character. It was claimed that Messrs. PEARSON used the ground beneficially and therefore were bound to pay. Everybody who passes through Greenwich, or who stays for a night in one of the hotels, could also be said to enjoy a beneficial occupation, and there are places where the briefest enjoyment of residence involves liability to taxation. But that is not the English practice, although many people would desire to see so annoying an incidence in operation. One reason for exemption is that taxes cannot be levied in equitable proportion on permanent and temporary occupiers of ground and houses. If the latter are allowed to be exempt, some of the former, who may be absent and enjoy few advantages from authority, have to pay, so that ultimately a fair balance is struck. Again, builders and contractors rarely work on land that is their property, and if the owners are assessed, as they should be, why are the contractors expected to pay in addition? Looked at in a broad way, such applications as that to Messrs. PEARSON & SON are unfair. But the magistrate considered the question was worth consideration, for he reserved his decision. It was given on Tuesday, and of course was in favour of Messrs. PEARSON; but there was still some uncertainty in Mr. KENNEDY's mind, for he declined to give them costs, and offered to grant a case to the applicants for taxes. If Messrs. PEARSON are not liable, we see no reason why, because they are contractors, and are entrusted with a perilous undertaking, they should have to go through the ordeal of a police-court inquiry at their own expense. The money may be a trifle, but the principle at stake is important, and affects all builders and contractors in this country, for they should not be exposed to litigation which can be set in motion with impunity.

THE working plans for the drainage of Chichester have been completed by Mr. BALDWIN LATHAM. The estimate for the works within the old city boundary and outfall works is 24,400*l*. It is proposed to extend the city, and to provide for the new parts a further outlay of 6,350*l*. will be needed. Originally it was proposed to convey the sewage to New Fishbourne and, after treatment, to discharge the effluent into Chichester Harbour. Owing to the opposition of the fishermen it is found necessary to adopt another site, but it will be a very much more difficult and expensive matter to get the sewage there than it would have been upon the site originally selected. In order to properly command the new site with advantage, it will be necessary to put in iron sewers along a part of a public road. Mr. BALDWIN LATHAM proposes that the sewage, after treatment within the buildings proposed to be erected, will be allowed to subside, and the clarified effluent will then pass over an area of land laid out specially for the purpose. This effluent will be retained in a tidal storage tank, and discharged into the Chichester Harbour only in the first period of the ebb-tide. The effluent produced by the proposed sewage treatment will be as good as is usually secured in any inland district, draining into a fresh-water stream, the water from which may afterwards be used for the purpose of a public water-supply. There is no provision in the estimates for house connections. The engineer says that as a rule the cost of house connections, including the branch drain to a house with an intercepting

trap and proper cover for examination at the street kerb, would cost about 45*s*. each. It is for the Corporation to determine whether or not this work should be carried out at the time of the sewerage undertaking. This has been done so in a large number of instances in recent times, and the money sanctioned by the Local Government Board for this expenditure has been borrowed and paid off with the rest of the loans incurred. The arrangement has one great advantage, as it will very considerably relieve small owners of property from incurring heavy expenses in having to make house connections with the public sewer in the road, whereas, on the other hand, there may be a certain number of owners of property in Chichester who at present drain to the sewers, and under the Public Health Act of 1875 they may require the Sanitary Authority to make the house-drains for them at public cost. It will be necessary to have another inquiry before the sanction of the Local Government Board for borrowing the money can be obtained. Once more the whole subject will have to be discussed, and the opposition which hitherto has acted with a contentiousness that is without precedent can again show its strength. There can be no doubt, however, that the sanitary state of Chichester is discreditable to the ecclesiastical as well as the lay authorities.

THE proposal to found a library and museum in Horsham as a memorial of the poet SHELLEY, who was born at Field Place in 1792, does not appear to have much chance of realisation. The whole of the subscriptions do not amount to 300*l*. Much was expected from America, where the poet's works receive more appreciation than in England, but the committee have received only 72*l*. from the United States. The secretary says: "The money at the disposal of the committee is wholly inadequate to meet the expenses of founding and endowing a Shelley Library and Museum at Horsham. It has been suggested that in lieu of the library, the money actually received, where no objection is raised by subscribers, should be applied to the purpose of founding and endowing an annual prize for English literature at the Horsham Grammar School. To this the American subscribers have agreed. As, however, the original scheme was approved almost unanimously, it is only fair that wide publicity should be given to the actual state of the case; especially as even now there may be some who, rather than permit the larger project to lapse for the want of money, will be ready to come forward with the necessary funds." The reason for the indifference no doubt arises from the conviction that a library and museum cannot be of much use in Horsham, where so little has been done by the inhabitants to express their sense of the honour which comes from having a townsman like SHELLEY. If they were eager to see a memorial of the poet among them, they would have no difficulty in raising the money to pay for it.

IT sounds strange to have the name of ROBERT BURNS connected with a law-suit, but one has arisen over a statue of the poet. He does not stand in need of that sort of immortalising, but somehow his admirers consider there cannot be too many statues of the poet, and in consequence some of the strangest figures have been created as representations of the sturdy ploughman. In Providence, Rhode Island, a BURNS Monument Association was founded. A commission for a statue, which was to cost 15,000*dols*., was given to Mr. NOBLE, a sculptor, who lives in Boston. After a time he was informed that the project was abandoned. Mr. NOBLE claimed 6,800*dols*. for the work done by him, and as he could not obtain it he was compelled to bring an action to recover his money in the American Courts. The defendants relied on a variety of pleas. First, they tried to make out they did not belong to the BURNS Monument Association; secondly, it was argued if they were members it was arranged between them and the sculptor that the commission was to be valid only when sufficient money was subscribed; thirdly, that the 15,000*dols*. were not collected; and fourthly, that all the money which came in was handed over to the sculptor in return for his risk. The Courts took a simple view of the affair, and judgment was given in favour of the sculptor.

THE AMPHITHEATRE AT ARLES.

AN Englishman who wishes to see a Roman amphitheatre will of course prefer a journey to Rome rather than to Arles or Nîmes. The Colosseum is in length and breadth nearly one-half greater than the French examples, and it undoubtedly has more historic interest. It is well, however, to remember how vast was the difference between Rome and a sort of colonial capital. What seems surprising is that Arles, although it was the Gallic Rome, was able to obtain authority and aid to erect buildings so important as the amphitheatre and the theatre. Their size and character denote the value which statesmen ascribed to spectacles as an aid to government by supplying one of the necessities of life, *panem et Circenses*, for Romans. The belief in their efficacy still prevails in France. It is not only in Arles and Nîmes that remains of amphitheatres are found. They existed also in Bordeaux, Saintes, Poitiers, Senlis, Béziers and Fréjus. Nor was the predecessor of Paris without its arena.

At Arles the site was selected with judgment. Although the building has been freed from the houses which, like parasites, were attached to it (they were made up of its materials), yet as it is surrounded by streets, a visitor does not realise that the ground on which it stands is the highest in the neighbourhood. In fact, the slope of the site made it necessary to employ an immense mass of masonry in the substructure.

We suppose it can never be determined when the amphitheatre was constructed. It is probably as well the date should be unknown, for if a record relating to the work were discovered, there would be an end to the controversy among the archæologists of the South of France about the relative ages of the amphitheatres of Arles and Nîmes. Priority is claimed for Arles on account of a supposed refinement in the detail, which is said to indicate a period when Greek influence had not vanished. The less complete hydraulic arrangements are accepted as further proof of age. On the other side, it is contended that the superiority of the treatment which is visible in the arching, as in other parts of Arles, is evidence that the builders were novices when they erected the amphitheatre at Nîmes, and accordingly they were able to give the benefit of their experience to the work at Arles. In both places, any pride there may be in the quality of the masonry would be sacrificed if by doing so some assurance of greater age could be given. The amphitheatre of Arles may date from the beginning of the second century, but there is no historic evidence of its existence prior to the fourth century, for about A.D. 335 it is recorded that spectacles were held in it. The later emperors were disposed to keep the people in good humour, and during their brief reigns the arena of Arles was probably not allowed to be unoccupied. The early Frankish kings followed their example, but it is to be hoped without sacrificing the lives of human beings. The remembrance of those sacrifices was enough to compel Christians to have an enduring aversion towards the theatres in which they were enacted. The amphitheatre of Arles was doomed to ruin. The quantity and strength of the masonry were not easily overcome. Before the building was demolished Arles was threatened with an invasion of Saracens, and the people were glad to utilise the ruins and convert them into a citadel. When the danger was at an end the amphitheatre was again treated as a quarry. Fortunately Arles was a place of slow growth, and the stones were not required except for ordinary buildings. There were no palaces like the Palazzo di Venezia, the Palazzo Farnese, the Palazzo Barberini and the Cancelleria Vecchia, which were built with the stones taken out of the great Roman amphitheatre. During centuries the ruins were pillaged for mean hovels or neglected until the Renaissance gave interest to all relics of Roman greatness. The place was visited by FRANCIS I., who lamented the degradation he witnessed. HENRY IV. took a more practical view, for he ordered some of the buildings that were erected on the arena to be removed. At his death there was only a partial clearance, and then followed a fresh period of neglect. In the beginning of the present century, when Frenchmen were esteeming themselves as the heirs of the ancient Romans, interest was once more renewed in the amphitheatre, and the colossal work of clearing the ruins from rubbish was commenced. But

the squatters were less easily removed. There were over two hundred houses within the amphitheatre, and the occupants could not be evicted without compensation. It was considered to be a victory that at the beginning of 1830 one hundred and eighty were already demolished, at an outlay of 3,000*l*. The remaining thirty-one houses cost no less than 24,000*l*. Altogether more than 7,000*l* had been expended before M. QUESTEL was asked to report on the works that were requisite for the conservation of the amphitheatre.

It is evident that the elliptical plan of the Colosseum in Rome was taken as a model in the provinces of the empire, but the ratios of the axes differ slightly. In Rome the major axis of the ellipse, measured to the exterior, is 616 feet, and the minor is 511 feet, or 1 : 1.20. In Arles the axes are 446 feet and 353 feet, or 1 : 1.26; while in Nîmes the axes are 433 feet and 332 feet, or 1 : 1.30. The arenas of Arles and Nîmes are almost identical in size. The former measures 227 feet by 130 feet; the latter, 227 feet by 127 feet—a correspondence that cannot be accidental. As the ratio of the inner ellipse was about 1 : 1.8, the occupants of the lower seats possessed not only a closer view of the scenes in the arena, but they were able to see easily across "the house," and to recognise acquaintances in opposite tiers. Owing to the corridors being of uniform width the ratios between the axes were altered, and accordingly the upper tiers of seats were not only farther from the arena than those below, which was unavoidable, but as the ellipse gradually approached the circle (since the minor axis was increased in length at a rate that was impossible with the major axis) the occupants, in proportion to their inferiority, were kept more apart. The elliptical plan was probably adopted in order to suit the convenience of the most important people in a Roman city. If the seats were arranged on a circular plan (assuming the length of the arena to be the same) there would be fewer chances for the occupants of the *podium*, or row of boxes, to exercise themselves in the language of the eyes.

There were discoveries at Arles which enable us to realise some of the arrangements of the podium. That part of the amphitheatre was faced with marble, and was divided so as to form a series of boxes, which were assigned to officials, corporations, and other people of importance. At Arles the divisions of the podium did not rise from the ground, but rested on a sort of cornice which was carried by walls. It is supposed that a sort of wooden gallery was built in front of the podium, which could be used as a refuge by the *bestiaires* if they were pursued too closely by the wild animals. In the modern circus the performers, when they wish to suggest they are in danger from a trained mule or other quadruped, vault among the audience, but Roman senators and commanders would not be so tolerant of the presence of men who fled instead of combating. The gallery could also be safely used by the *grandees* when they goaded the animals on leaving the cages. That combats with lions, tigers and panthers were more common in the amphitheatre of Arles than at Nîmes is evident from the height of the podium we have described, which no wild animal could bound over, as well as from the remains of the animals which have been found in the subterranean chambers. Two inscriptions are also to be seen in the Musée of Arles, which relate to contests of gladiators and *bestiaires* that were provided at the cost of two of the *grandees* of the colony.

The exterior of the amphitheatre of Arles presents two storeys or series of arcades, the lower being Roman Doric and the upper Corinthian. It is assumed there was also a very low attic on which the blocks used for supporting the *velarium* were built, but there is no trace of the arrangement, Arles in that respect being less fortunate than Nîmes. It is still possible to appreciate the arrangement of the plan, which was so simple that few of the 25,000 spectators were likely to be puzzled in reaching their prescribed places. The principal entrances were at the ends of the major axis, and from them a gallery led direct to the podium, which contained four rows of benches. There were three other divisions, each having eleven rows of benches, which communicated with corridors and staircases leading to the external arcades. The subterranean part had also its passages to and from the outside world. There is some cylindrical vaulting in one of the galleries, but on

the whole the construction imposed no great difficulties on the masons. The massiveness of so many of the stones is characteristic.

It is remarkable that the theatre of Arles, of which only enough remains to suggest the splendour of the building, is supposed to owe its ruin to the portability of the stones which were employed in it. Built of stones as large as those seen in the theatre at Orange, it was likely to have as well withstood the wear and tear of ages. We have cause, therefore, to be grateful to the builders of the amphitheatre who insisted on using such a quantity of large stones in the amphitheatre, although it was necessary to convey them from a quarry that by the route taken was twenty miles distant.

ARCHITECTURAL ASSOCIATION SOIREE.

Production of a new and original Medley, in a Prologue and Two Acts, by Theo. Moore and Ernest Rüntz. Played for the first (and last) time at the Westminster Town Hall on Wednesday, May 17, 1893.

"MYTHOLOGY RUN MAD; OR, LES CHUMPS DE MARS."

[BY A CORRESPONDENT.]

EUREKA! Mr. Editor—Eureka!! "The place where good architects go." The planet Mars! No need any longer of vain speculations as to signals and flash-lights for communication with that blissful sphere. The Architectural Association have organised one of their inimitable excursions into the land of the great departed, and by the help of Messrs. Theo. Moore, Ernest Rüntz, and other Searleswood imitators we were presented with a slight idea of what the excursion might be if we ventured ourselves by the Lightning Streak Railway, at the reduced rates which the Hon. Sec. has managed to arrange. Hitherto the attractions of the A.A. excursions have been set forth by magic-lantern diagrams, but now they are modelled in the solid.

PROLOGUE.

(Air.—"Once more I sent the needful eighteen stamps.")

I.

MERCURY. Whenever I purchased the *Builder* I scanned the advertisements well

To see if assistance was wanted by some architectural swell;
For one quid a week and my washing in his office when left all alone,
I'd turn out a fine set of drawings you bet, which he'd promptly annex as his own.

Such things on earth I find are still the same,
Assistants oft-times make the master's name,
For overtime they are not paid a sou,
I'm blest if I'd put up with this, so take my tip—don't you.

II.

Well, I passed as a district surveyor, fixed screws were unknown in those days,

And then I gave lectures, wrote booklets, for the use of professional J's;
Through the ranks I a colonel became, and later an M.P. was made,
A professor you see, tho' without a degree, I'm a hot 'un at pushing my trade.

Once more I've spouted at the Joiners' Hall,
Once more defined a legal party wall,
Once more idealised ancient lights,
With pride I swell, as you can tell, at arbitration fights.

First, of course, we were shown the starting-point on this side, a Railway Terminus, designed by the Soane Medallist, and, as the greatest attraction to the A. A. man, the bar was to the front. Mercury, acting as barmaid to the passengers, after their departure announces his mission thus:—

Well, this is strange; I seem to know the place,
And yet I'm straight from Mars, by special grace
Of Jupiter—a tedious old bounder.
For him I seek a wife, and when I've found her,
To Mars above I will be her purveyor.
When in the flesh I was district surveyor—
What R.A.'s call an architect's policeman!
Of course, I took a fee on this.

Cupid then appears, entrusted with the mission "to find a mash for Mother Venus." The "mash" appears in the person of Colonel Jonathan Gin Cocktail, of Chicago, who has "come from the World's Fair to buy the Tower of London and St. Paul's Cathedral (bar the reredos, which should be Bod(i)ley-Garnered to its long home in the Aquarium)," also "Haddon Hall and Hatfield and Blenheim, where the battle was fought." Jonathan is induced to go to Mars by the prospect of buying up the planet for the Chicago Show, Mercury selling him the ticket, as he "bought them up in Mars, and pretty cheap"—

Because the owners never will return
A batch of builders. Man, how they will burn!

Then enters Mrs. Moriarty, of Dublin, mother to Venus, together with her nephew, Leonard Aloysius, a poetic craftsman. Leonard Aloysius had started with the idea of taking his aunt and his sister Josephine on an A.A. excursion to Italy, but repents thus:—

Why ever was I fool enough to take these two impossible women with me? All the way to Italy, too. I'm mad! (*To CUPID, acting as porter*) Is this the platform for the A.A. excursion to Earlswood? I mean, is this (S) Earlswood Station for Italy?

CUP. Searle's Wood! He'll be here directly. He's at an R.I.B.A. examination, helping on the nervous A.A. men. (*Applause.*)

Then Leonard sings (Air—"The Man that Broke the Bank at Monte Carlo") :—

I.

To Italy's fair sunny climes some members fain would fly,
With Searle's Wood and Company, just to wink the other eye
At architectural marvels and brunettes so sleek and spry,
And an ice cream to satisfy the inward man,
Varied by some macaroni and some jam.

Chorus.

And as they walk along with this mixture so strong,
Concealed somewhere there (*under waistcoat*),
You will hear the girls declare
They have had a bad nightmare.
You will hear them sigh and wish to die,
As they blink and wink their bilious eye,
In a way suggesting "Wells" of Monte Carlo.

II.

I've heard the A.A. meetings are not patronised of late,
Well, they're not quite up to date, and I've heard our friend Stokes state,

He would like to suck his pipe and take a pint whilst on debate,
And I think 'twould suit the members very well,
Judging by the bad tobacco I can smell.

Chorus.

Thus they'd jog along and the meeting prolong
Until morning's chilly air,
But little would they care,
So long as the booze was there,
And the papers they'd try, in the sweet bye-and-bye,
To discuss with a song and a sleepy eye,
To the tune of "Twiggy Vous" or "Monte Carlo."

Josephine then enters with a box, soliciting "a mite to our headquarters," and after colloquy, chiefly oburgative on the part of Erin's daughters, between Mrs. Moriarty and Leonard Aloysius, sings a duet with Mercury which runs thus:—

Duet—MERCURY and JOSEPHINE.

(Air, "I'm in love with the Man in the Moon.")

I.

MERC. May I ask, miss, if you have a lover?

JOS. I'll refer you at once to my mother.

MERC. For I've plenty to furnish a trip to the stars,
(*Aside*) (In the wrong train I'll put her, it's just off to Mars,

The old lady I'll lose, for her accent it jars.)

JOS. (*To Jos.*) And your name you shall change pretty soon.
You're rather too previous, for I'm not yet game,
To take you—unknown—as my regular flame.
I must ask you to furnish me, sir, with your name,
For you might be the Man in the Moon.

Chorus.

Yes, he might be the Man in the Moon,
But we'll find out the truth very soon.
His manner is light, and there's something not right
In his conduct suggesting a heavenward flight.
On this evening of May—to the tune
Of in love with the Man in the Moon.
And she's (*points to Jos.*) falling in love with this man from above.
You would think she'd prefer a dragoon—
Yes, a handsome and dashing dragoon.

II.

MERC. Well, a soldier I'd be for your pleasure.

JOS. I'll inform you my wishes at leisure.

MERC. Architectural policeman I've been all my days,
I delight in enforcing the Building Acts' ways,
And to spoil a fine building is my special craze,
But I always find time for a spoon.

JOS. Prompt payment of fees is a very good plan.
If you stick to this course, I may have you, young man,
Though for Art and Art culture you don't care a (*drum*),
Any more than the Man in the Moon.

Chorus.

Oh! we knew she'd discover it soon—
He's a policeman and not a dragoon.
So of course it's all right, though his manner be light
His professions are proper, his language most trite.
When on Italy's famous lagoon
As our courier he'll prove a boon.
With such brilliance and wit, why he's not the least bit
Like a man that resides in the moon—
Such a man cannot come from the moon.

Leonard Aloysius, having missed the train to Italy, decides to go to Mars to see the Acropolis. Mrs. Moriarty is attracted by the chance of seeing her daughter Venus, and—

The blayguard who killed me darlin' Pat. Ah! Mr. Mercury, he was an Architect, but he was always studyin' a book they call "Gwilt," an' it kilt him intirely.

MERC. Gwilt! Why there's a man of that name upstairs. (Aside) Won't there be ructions!

Josephine also is ready to go, as she says in her song—

(Air—"Oh! Mr. Porter.")

JOSEPHINE.

Lately I just spent a week of play and Ta'rara booms,
Went to a dance with A.A. men at the Portman Rooms.
Just a time I had of it, and once came a cropper,
The Lyric boys all turned their heads and murmured how improper.

Leaving half a waltz undanced I started for the station,
My mash saw me to the train, the needful did fork out,
Bought my ticket, said good-bye, kiss me, ducky (*smack akiss*).
Oh, my!

But I found the train was wrong and shouted out:

Chorus.

Oh! Mr. Porter, these are not the cars,
For I want to go to Brixton, and they're taking me on to Mars;

Oh, send me back to London as quickly as you can—
Oh, Mr. Porter, what a silly girl I am!

II.

My living I don't want to earn, but mother says I must;
She says, unless we get some oof our home will simply bust,
But when I have a brother here (*points to LEONARD*) it is extremely hard

That I should work and he should laze and do the lardy dard.
Typewriting I've taken on and dued my hair in fashion,
For a taste of matrimony 's joys I yearn.
And now I'm off to Mars above, I'd better cultivate true love,
And hope a lonely girl immortals will not spurn.

Chorus.

Oh! Mr. Cupid, what shall I do?
I want to find a husband, and of course I look to you.
Trot me out some Greek gods as quickly as you can,
They're better than none, but for frivol and fun
I much prefer a man.

Thus all is prepared for the A.A. trip to Mars, and thus they express their intentions:—

CUP. So, we're all for Mars. I've been and nicked him (*points to COCKTAIL*).

Behold my triumph, this is Venus' victim.

MERC. And I have booked this skittish old Hibernian (*points to MRS. M.*),

For Zeus to ogle over his Falernian.

MRS. M. I'll go to Mars and see me daughter queen.

I really want a shmoke, where's my dhudeen?

JOS. If I go there my prospects will be brighter,
For I'm Theosophist, Masseuse, and Typewriter.

LEO. And I'll go there to preach my Art and Letters,
And teach the Gods how to respect their betters.

COCK. And I to buy the planet for Chicago.

Let's have a drink, so all unto the bar go.

Which they do, singing a new version of the Association anthem, "Troll, Troll."

Chorus.

Troll, troll, bonny brown bowl,
A lass and a glass and a friend for me;
This is the toast all good fellows boast,
Whether of high or of low degree.

II.

LEO. Rhyme, rhyme in sunny clime,
Why should a poet not dream all day?
The better the sort of a kind of a thought
The sweeter the drink when the sun's away.

III.

JOS. Sigh, sigh and pipe the eye,
Why should a woman not woo a man?
I'll go to the skies and mesmerise
All lovers defunct since the world began.

IV.

Mrs. M. Hurroo for Brine Boru!
I'll go and see me daughter queen,
And I'll lay odds the murderin' gods
Will soon be a wearin' o' the green.

V.

MERC. Flit, flit to realms lovelit,
The lightning streak is on the move.
A button we press, in a second or less
We'll be taking some tea with the Queen of Love.

Of what happened when the A.A. party joined the Immortals in the sphere of Mars we must tell next week.

NUNRAW CASTLE.

THE following paper—the last he was destined to compose—was read by Mr. John McLachlan at the visit of the Edinburgh Architectural Association to Nunraw Castle, Haddington:—Nunraw was, as its name indicates, a nunnery before the Reformation, and was an appanage of the abbey of Haddington. That abbey was founded and endowed in 1178 by Ada, Countess of Northumberland, who was the mother of two of our Scottish kings, Malcolm IV. and William the Lion. Chalmers, in his "Caledonia," informs us that "the Church of Garvald with its pertinents and a carucate of land adjacent were granted to the Cistercian nuns, which the Countess Ada settled near Haddington during the reign of Malcolm IV. They established a grange near the church, and formed a village, which thus obtained the name of Nunraw. They also acquired the lands of Slade and Snowdown, forming together almost the whole parish of Garvald." We find in the story of the nunnery that James II. granted to Dame Elizabeth Hepburn, prioress of the Abbey of Haddington, a royal charter to "fortifie the nunnery and to make it into a fortalice or castel, and to have guns aye loaded to shoot at our alden enemies of England." The church of Garvald, and the large extent of territory above indicated, remained with these opulent nuns until the Reformation, a period when many a fair estate was lost to the Church and the general good to satisfy the lust for land of the ancestors of many of our great families. We can sympathise with the indignant denunciations by John Knox of the wholesale robbery of the Church lands by many of the very men who professed to hold up his hands as the Apostle of the Reformation.

At this time the nunnery and lands came into the possession of the family of Hay, in whose hands it remained until quite recently, about 1865. The Hays were thus in possession of the property for the long period of 300 years. Of the family, history says little or nothing. They no doubt discharged their duties and responsibilities as landowners in a becoming and fit manner. One of the most recent members of the house, of an artistic and architectural turn, became possessed with the idea of restoring the building to the condition in which it originally had been. This was about the year 1860. He called to his aid the assistance—the professional assistance—of one of the most able and charming members of our profession in my time. I mean the late Mr. Wardrop. The house before us is the result. Mr. Hay did not live sufficiently long to see the result of his endeavours to restore the old fortalice. He died in the midst of his schemes of restoration in 1863. The idea of restoration, however, was handed on, and Mr. Hay's son carried on and completed the schemes projected by his father. This was in the year 1864.

The work done by Mr. Wardrop is excellent of its kind, as everything he did was excellent and scholarly. No one could desire a more excellent reproduction of an old building. Every detail, the hinges and locks of the doors, the carved panelling of the doors and shutters, the oak floors, the ceilings of timber, the solid walls, the absence of all strapping and lathing, the ironmongery—all these details, in addition to the general arrangement of the house carried out on the lines of an old Scotch mansion house, with the modern requirements of additional light and space—all these points show the work of a genuine artist, and I rejoice in this opportunity of paying a small tribute of admiration to the work of a professional brother, as I do most heartily to this work of our late friend, Mr. Wardrop. At the same time it remains a question whether restoration has in this case not been overdone. Scarcely a vestige of the original building remains visible. The central tower is almost all that remains. All the rest has been veneered with new red masonry and rearranged and transmuted, so that it is utterly impossible to define what is old and what is new. It seems to me that with our modern and, as I hold, correct notions of dealing with an old building of this class, it would have been wiser to retain the old building practically as it was, doing such repairs and works as were necessary to preserve it from decay and make it useful, if that was possible, as a portion of the mansion house, at the same time retaining its distinct individuality as the original structure. The sentiment of having a hoary building with five centuries of legend and story beside you—veritable undeniable history in stone—is worth all the comforts which modern architecture can devise. I do not press this point, however, as I know there is considerable diversity of opinion. I shall express, however, and I express it confidently, as I am sure it is the opinion of you all, that it is a pity that Mr. Wardrop has preserved so little of the old building.

In the course of the renovation a discovery of great antiquarian interest was made in 1864. In removing the ceiling of the then drawing-room, and while the plastering, lathing and strapping were being removed, a second ceiling was discovered consisting of oak joists placed about 15 inches apart, and the wooden boards nailed upon the oak joists. These joists and the long panels between the joists formed a groundwork for the decorator of three centuries ago, and the result is that we have

before us a painted mediæval roof entirely covered with an endless variety of figures drawn with great freedom of hand, and in great variety of colour, as fresh and vivid as the day on which they left the hand of the artist. The apartment in which these interesting remains of painting were discovered was a large and important apartment measuring about 30 feet by 18 feet, and about 16 feet in height. The conclusion came to with regard to the apartment, from its size and consequence, was that it had been the refectory of the nunnery where, as Mr. Croal says in his admirable guide-book, "once or twice a day at least, all the sisterhood met the Lady Superior, and where they partook of the liberal cheer that helped to compensate for the solitude to which they had voluntarily consigned themselves." Describing the panels, Mr. Croal says:—

In one place, not far from the door, was a large receptacle neatly hewn out of the stone, that possibly in its time had held good store of the French wines that were then in use. Be this as it may, the manner in which the hall had been adorned leaves little room for doubt as to the cheerful purposes for which it was used. Fourteen strong oaken joists span the ceiling crossways to its length, the whole of the exposed surfaces of which are painted over in stripes of lively colour. No deafening having been used in those times, the intervals between the joists formed so many long panels the entire breadth of the roof, on which the inventive genius of the decorator had been exercised with much taste and skill. The most prominent object in each of these panels was the title and armorial bearings of the monarchs who flourished at the time. There had been originally twenty-eight of these, two for each panel, but several were now defaced, in some cases from damp, and in others from the ceiling above having been cut open by one or other of the modern proprietors of the house. By far the larger number, however, were in perfect preservation. Beginning with the east end of the ceiling, the first panel contained the titles and quarterings of "The Emperor of Rome" and "The King of France"—the other portions of the space being filled up by lively representations of birds, animals, mailed hands and allegorical figures, of which cupids or angels, it was difficult to say which, stood out most prominently among the number. The next panel contained the titles and armorial bearings of "The King of Scotland" and "The King of England"—the lion rampant of Scotland and the three lions passant of the sister country being very boldly represented. There was here again introduced a variety of figures, some of which, from the oddity of their appearance, could be claimed by neither earth, sea nor sky. The other panels were filled up in a similar way; and some approximation was to be obtained to the date of this curious ceiling by the occurrence of the titles of "The King of Navarre" (Navarre) and "The King of Arragone"—kingdoms which for the last three centuries at least have been incorporated with that of Spain. Other panels contained the titles and quarterings of "The King of Denmark," "The King of Portugal," "The King of Sweden," "The King of Cecilia" (Sicily), "The King of Friesland" (possibly Holland), and several others of which the names could only be guessed at. "The King of Egypt," however, was very distinct, his armorial bearings being represented by three serpents. In the centre of the roof the words "GRATVS ESTO," in Roman letters, were visible, along with the monogram "P. C. H." The figures which filled up the other parts of the panels were of every possible character—heraldry, with its endless tribe of griffins and other monstrosities, having been laid under contribution to supply subjects for the fertile pencil of the artist. Among the other figures occurred four representations of the "human face divine"—two male heads and two female. They are painted with much freedom and vigour, and were possibly intended for portraits of the founders of the nunnery. One of the male heads was crowned, and not improbably represented that of David I.—that "sair saunt for the Crown."

One interesting point about this ceiling is that a considerable portion of it is to be seen in the Antiquarian Museum of Edinburgh, and that portion shows what purports to be the heraldic representation of the king of Egypt with three serpents. The probable date of the ceiling is about the end of the sixteenth century, the time of James VI., say 1570 or 1580. We have two or three well-authenticated ceilings of the same date—one of an old house in Linlithgow of 1570, and the other of the large upper room in Pinkie House which we visited some years ago, and is undoubtedly about the same time.

PHOTOGRAPHY IN COLOURS.

IT was announced once again the other day, this time from Paris, says the *Standard*, that photography in colours had been achieved, and that specimens of that fleeting art were on their way to the Chicago Exhibition. The telegram which we print from our Paris correspondent this morning shows that what M. Lumière has really done falls very far short of the scientific feat attributed to him. There has scarcely been a year since the goodly art of sun-picturing began in which sanguine persons have not been led to indulge in great expectations regarding the accomplishment of what may, without exaggeration, be described as the one great thing still left undone before photography can be considered perfect, even in the imperfect way in which the laws of nature can be made subservient to human art. It is barely a year since Mr. Ives, an ingenious American, was exhibiting to us beautiful specimens of what were popularly described as photographs in colour,

though perhaps it would have been more accurate to consider them as very interesting specimens of optical illusions. At all events, Mr. Ives's exhibits at the Royal Society's conversazione and at the Royal Institution's evening lectures were not what the longing world means by photography in colours. That is to say, they were not impressions on a sensitive plate of all the hues of the scenes presented to it, just as we see in a negative all the minutiae of the same objects represented in black and white. When the photograph is produced which exhibits a reproduction of what is reflected on the ground-glass "back" of the camera, then this goal will have been reached. But that, for reasons good and sufficient in the present condition of optical and chemical knowledge, is not likely to be accomplished. Nor, of late, has it been seriously attempted. The experimenters who aim at coloured photographs seek success rather by pressing the laws of optics into their service, and so far promise better results, though their photographs, whatever they may be called, are, as we have said, more or less optical illusions. But as all the beauties of colour are simply the effects of light playing pranks with our optic nerve, it matters very little what we call the plate so long as it reproduces in an approximate form what is presented to it. The image in the camera was familiar enough to thousands before Daguerre—or the nameless youth who left the completed result in Chevalier's shop and never returned—managed to fix it. It would be rash, therefore, in spite of many failures and an infinitude of quackery, to assert that the photographers who are struggling in search of this evanescent possibility are mere dreamers of dreams. The one thing which makes photography regard its present victories as poor compared with its future triumphs will, no doubt, before the next century has passed its first decade, or even before this one has ended, be as familiar to us as photography in black and white is to-day, and be regarded by the next generation as a matter of course.

The latest specimens of photography in colours seem to mark a distinct advance upon anything which has preceded them. Taking the account as it stands, we may assume that M. Lumière—apt name for one who has so adroitly pressed light into his service—has produced something very remarkable, which, at all events, has all the appearance of what it claims to be. One of these pictures represents a bouquet, with red, violet, green, blue, and other colours in their various tints. A second, in its way even more striking, because the focussing must have been more difficult, gives part of a park with a blue sky, gravelled avenue, and trampled soil. A third plate shows a cottage in full sunshine, surrounded by shrubberies; while a number of others portray—all, it is claimed, in their true colours, and direct from the objects photographed—bright-hued placards, Japanese screens, and the like. So far the tests seem fair enough—if everything is as the operator affirms, and no doubt believes it to be. Hitherto, he admits, he has been unable to multiply any picture. As was the case with the old daguerreotypes, each plate must be unique; the art of taking proofs on paper is still a discovery of the future, though not one of anything like the importance of that which M. Lumière claims to have brought so far on the way to practicability. Nor is it at all likely to be popular with the "sitter" for a portrait. For, in the present state of the art, the half-hour's pose which is demanded would be almost as tedious as the early sittings for daguerreotypes. These photographs will, if not as disappointing as their predecessors and as evanescent, be deservedly associated with M. Lumière. But in reality they are simply improvements on those of M. Lippmann, an eminent French physicist, which some years ago created at first a certain scientific sensation, followed by much disappointment as a result. The experimenter, it may be remembered, photographed the spectrum in colours, painted windows and the like. Now, M. Lumière has advanced a step by simplifying the process. At the same time, it will seem to most photographers a little doubtful when his process is described as simply taking the views on "prepared gelatino-bromide plates equally sensitive to all colours." A mirror is placed behind the plate, and "the conflict of the incident and reflex lights produces alternations of light and shade resulting in a chemical phenomenon allowing a photographic delineation of the object." This seems, as a description, very like "drinking tea by stratagem," or "telling the clock by algebra," and yet it is decidedly too simple to solve the gigantic problems presented to us. For the great difficulty is to cover a plate with a chemical which is "equally sensitive to all colours," and, in any case, even if photography in colours has been accomplished, it is idle to expect the bright tints of nature, since, as Captain Abney pointed out long ago, these are, as a rule, produced by sunshine, whereas on the plate they have to be viewed by diffused light.

M. Lippmann's was, nevertheless, the first true departure on the right track, and, so far as we have seen, still remains—with M. Lumière's improvement—the most promising. His results, however, did not escape severe criticism. They were stigmatised as simply specimens of iridescence—that is to say, their colours were due to the same causes as those

which produce the spectra on a piece of mother-of-pearl or on a soap bubble. This is perfectly true. Yet, when viewed at the proper angle, the spectrum tints were really very brilliant, though decidedly dull compared with those of nature. It may also be remembered that, apart from this fact, they were to a certain extent mechanical, being produced on a laminated surface, a *modus operandi* suggested but never carried out by Lord Rayleigh as early as 1857. M. Lippmann, it is, however, proper to add, never affected to claim for his work the status of "photography in colours." It was simply a pure spectrum produced by a strong light, not the photography of composite colours reflected from natural objects illuminated by diffused light. Yet even at the time authorities as unimpeachable as Professor Meldola were confident that he had accomplished much, and in the direction he had taken might accomplish a great deal more. Whether that eminent chemist will consider as favourably M. Lumière's discovery an advance in M. Lippmann's track, or a divergence from the path suggested by him, remains to be seen. Mr. Ives's pictures were pretty. But neither did this experimenter claim for them any higher rank than that of a superposition of coloured pictures produced by mechanical means, imitating a natural effect. He never pretended, except in the inflated reports of his countrymen, to have solved what Professor Meldola calls "the photographic problem of problems." It is no doubt true that photography in colours is surrounded by so many almost insurmountable difficulties that it is excusable to regard it as unattainable, although we must not fail to credit M. Lumière with the service he has done to his art in making what our Paris correspondent describes as almost perfect photographic plates. But he has not found a practical solution of the problem of colour-photography. A score of similar claims have been made within the last thirty years. Indeed, it is not long since a certain Herr Verescz, of Klausenburg, in Transylvania, was vouched by no less an authority than Dr. Eder, of Vienna, as having all but reached the long-sought-for goal. He actually produced proofs in natural colours, but was unable to retain any except those between deep red and orange. Even these, if exposed to light, faded in from two to three days. This seemed the crux. Herr Verescz had not attained what he aimed at, and the result has been that we have heard no more of the Transylvanian photographer than we have of the many experimenters who preceded him in the same line.

PHOTOGRAPHY AS AN AID TO ART.

AT the meeting for the distribution of prizes to the students of the Art Training School, South Kensington, an address was delivered by Mr. W. F. Yeames, R.A. He pointed out that the standard of work required from artists was getting higher every day, the competition, owing to the increase of their number, being also very much greater. Students must always bear in mind that the instruction received in schools was always technical only, and that they were but on the threshold of art when they left the school, and must depend for success upon their individuality. When they entered into their work in the field of art they would come under many influences, and it was on one of these he wished to dwell, that of photography. Photography had done a great deal, especially for art. In one branch it had been an enormous help in the reproduction of the works of fine art throughout the world. Photography was a feature of the age of science and mechanical appliances, and, like all things scientific, dealt in facts. In no photograph did one see any expression of the emotions of the heart; but these were qualities which they, as artists, would have to deal with. In a broad way he would say the art of drawing had improved under the influence of photography, but he would make a slight exception as regards the rendering of human form and face by the great masters. He could not say that photography had excelled the productions of these great men who had such a keen perception of everything in nature that they were able to produce results that photography had never surpassed. But with nature in general, vegetable life, clouds, &c., photography had brought to light many things not known before. With reference to when and how students should use photography, he said the artist could use it with impunity when his knowledge enabled him to do without its services: that is, a man should be master of photography, and not photography master of the man. Before using it he should be so well grounded in the technique of drawing as to be able to draw any object in nature; photography would then be of much use to him, as it would lighten his labour and extend the range of his subjects. Photography should be used only as an aid to art work.

ANOTHER magazine for juveniles has been started by Mr. Henry Potter, 211 New Kent Road, under the title of "Pleasure." The first three numbers for March, April and May have been forwarded to us. Though the price is only one penny, the matter has been so well selected that it cannot fail to interest youngsters.

TESSERÆ.

William Hogarth.

IN his life not less than in his works, Hogarth presents a sturdy protest against all previous styles. No man more distinctively and decidedly original and creative—not even Phidias of Athens or Giotto of Florence—ever handled art; no one, for good or for evil, was ever less affected by pre-existing influences or by contemporary criticism. The modern art of Europe began as completely with him as its modern poetry with Dante; and as Dante's fellow-countrymen were at first unable to believe that a great poem could be written in their mother tongue, so Hogarth's were incredulous that England could produce a painter. He first, with a serious and widely-extended scheme, put into painting what Fielding put into novel-writing; he brought the canvas down from mythology and pageantry and made it tell the real story of common life—its pathos, its meanness, fashions, humours, tears, laughter, triumphs, and depths of degradations. Clowns, fops, lords, rebels, politicians, gamblers, labourers, soldiers, brides, mistresses, spendthrifts, poets, musicians, madmen—nay, the very wigs and queues and walking-sticks of the age—all move and live on the stage of his marvellous theatre. In a sense true of no other artist, Hogarth held up his mirror to nature, and gave back the form and pressure of the time with a strength only equalled by his subtlety. Shakespeare (always exceptional) excepted, no artist, not even Crabbe, has drawn so many characters for us, has given us so much healthy laughter, so much of "the sorrowing by which the heart is made better." Yet, in this prodigality of power one thing is wanting—not perhaps to his mind, but to his pictures—the charm of beauty is not conspicuous here. Occasional touches of grace or repose occur, the severity is not without sweetness; yet the higher sphere of loveliness is hardly reached, there is no clear sense of the poetry of nature. Through his stern, honest-hearted rejection of Italian art, abused and ill-estimated as he saw it by the men of taste about him, he missed this gift in marked intensity.

Greek Painting.

The earliest notices of Greek painting depend almost entirely on tradition or casual mention. To divest them of their ordinary fanciful accompaniment would be to deprive them of some very poetical idea congenial with the times, the subjects, or the associations with which they are so intimately blended. We should be sorry, for example, to abandon the fabled origin of the practice of the simple contour which, as Pliny informs us, arose from the fact that Gyges, the Lydian, observing his own shadow cast on a wall, immediately outlined it with a piece of charcoal. Notwithstanding the physical difficulties of the situation, the story is in keeping with the poetical genius of the remote period to which the incident is ascribed. The simple monochrome of the school of Corinth announces a further advance in the early practice of painting, of which, if no mural or movable tablet exists, it is yet attested through the instrumentality of the fictile vase. If the charms of colour or light and shade do not exist in these vases there still remains the power of specifying beauty of contour in the various effects of the different passions on the human form. It is also easy to express differences of race as well as physiological and other peculiarities. But it was not long before attempts were made to enhance the simple contour by the introduction of colour, and as we again learn from Pliny, Cleophrastus, the Corinthian, was the first to avail himself of chromatic agency by employing in his designs the ground fragments of a red potsherd. Attempts at perspective were beheld in these *catagrapha—oblique imagines*—attempts at foreshortening the discoveries of Cimon of Cleonæ. Subsequently came Polygnotus and his school, whose historical pictures adorned temples and porticos. Some of these applied principles of linear and aerial perspective, or at least of sciagraphy, with the illusive powers which they contribute, to the realisation of scenic effect and to the decoration of houses. Apollodorus and Agatharcus carried these arts to great perfection. Even earlier than the days of Sophocles these appliances are supposed to have been cultivated. The resources of the art were now being increased by the aid of science, which supplied additional powers, by whose means the fascinations of illusion conciliated and won the popular favour. The rivalries between Zeuxis and Parrhasius prove the extent to which imitation was carried, as well as the value attached to it by public appreciation. *The Hand of Alexander holding the Lightning*, by Apelles, so well foreshortened that it appeared to project from the picture, is another evidence of the application of scientific principles. Like other fables, they point a moral, and prove to us, that there were then, as now, persons who attached an undue importance to the mere realisation of imitative truth. As an evidence of the extent to which nature was studied, they may be accepted, but we are not therefore to believe that these artists based their claims to renown on such humble views. The fame of Zeuxis was established on more solid grounds. His celebrated single-figure pictures of Juno,

of Venus, of Cupid and of Marsyas were all of high repute. That he was fastidious also in his endeavour to embody character we know from the account of the variety of models he employed for the production of his *Helen*.

Vulgarity in Painting.

Art is, in truth, a great tell-tale, and no painter can effectually conceal himself in it from those who understand its language. Of all the qualities of the mind there is nothing more sure to be betrayed by the pencil than innate vulgarity—no matter with how high an aim or with how much of learning or of technical power it endeavours to pass for what is lofty. On the other hand, a mind is sometimes discovered by the art alone to be much superior to any prejudgment that might be formed from our knowledge of the education or personal habits of the individual. Of this there is not a more remarkable instance than Morland, whose works display a natural refinement of taste which, as in the best Dutch art, is the more striking from the homely character of his subjects. When we look at his pictures, we must conclude that dissolute habits, which in the prime of life destroyed this extraordinary man, were in great part to be attributed to the denial of all education to him, excepting in his art; by a sordid father, and which greatly increased if it did not produce that shyness of manner which drove him from decent society to the alehouse and the stable; while it left him unfurnished with any resources of relaxation excepting in low indulgence. But whatever were the failings of Morland, and however to be accounted for, there is not the slightest taint of vulgarity in any work of his hand. He is often homely, often slight to a fault, and it is said he was employed by a patron to paint a series of immoral pictures—yet such is the refinement of his colour and his true feeling for the simplicity of nature that his works will always sustain companionship with those of Gainsborough, which can be said of no painter in the least degree vulgar. The essence of the vulgarity that is most offensive is pretension; and it therefore generally aspires to the high places of art where it shows itself in every species of false sentiment. It greatly affects the superfine—it produces the mock heroic—and all the numerous mistakes of the exaggerated for the grand and the poetic. The styles of Spranger and Goltzius are vulgar from their inflation, from their attempted imitation of art that was far above their powers of comprehension. Rubens, Rembrandt and Murillo are vulgar when they give us meanness of character where elevation is required. Instances from the works of the first and the last are close at hand—the Moses and Aaron in the “Brazen Serpent” of the former and all the personages in the “Holy Family” of the latter in the National Gallery—but the utter and most remarkable subversion of the art by vulgarity, for it was vulgarity mixed with the highest refinements of vice, took place in France in the reign of Louis XV. It began indeed under that of his predecessor, a monarch who fancied he showed his taste by ordering the works of Teniers out of his rooms.

Criticism of Modern Architecture.

A practice most disheartening to the architect, and one which is common enough with half-educated judges, is to base a judgment as to the merits of an artist (and an architect perhaps in particular) by comparing him and his works with others who, in the past under favourable circumstances, in which he never has been or could be placed, have produced more excellent works than his. To be continually using the names of the great masters of antiquity, and declaring that all men are feeble because they do not produce the same results that those great masters produced, is unjust in the highest degree, and exercises as ineffectual an agency as can be conceived for the introduction of general improvement. There may be errors in contemporary art, but it is not to be elevated by vague parallels between things which really do not admit of just comparison. “Art,” as has been well remarked by Dr. Memes, “has never been reformed, after a lapse from high eminence, by mere imitation of examples, however excellent, nor by only following rules for the correction of error. It is here, as in morals, that example succeeds where precept would fail. Some mind of uncommon firmness and good sense is required, who, beginning with nature, brings to the work of reformation original powers and severe judgment, fancy and feeling, with correct and cultivated taste—one in short of those rare minds whose merits, great in themselves, become incomparably greater viewed with the times in which they commence their career, and whose exertions, wonderful in their own accomplishments, are yet more admirable from the progress which thereby others have been able to effect.” If such be the influence of genius, it is surely the duty primarily of professional men, and secondarily of cultivated public opinion, to recognise such minds when, from time to time, they present themselves, and to aid, as far as may be, with no little-ness of envy or jealousy, the onward footsteps of those whose heaven-born gifts may fit them to lead rather than to follow. Nothing in history is more unsatisfactory and detrimental to real progress than to recognise in the lives of great men the

misérable jealousies and misapprehensions which have retarded them in their career, and militated against the good which, but for those drawbacks and that unreasonable friction, they might have effected. Happily architecture, as an art, is not as liable to unreasonable criticism as other branches of the fine arts. Its very firm alliance with utility, as well as with beauty, gives it a practical character which allows of the ready application of reason as an element in test and success or the reverse.

Stone under the Microscope.

It is often held that the best method of determining the probable durability of a building stone is to study its surface, or thin transparent slices, under a microscope. This method of study in recent years has been most fruitful in developing interesting and valuable knowledge of a scientific and truly practical character. An examination of a section by means of the microscope will show not merely the various substances which compose it, but also the method according to which they are arranged, and by which they are attached to one another. For example, pyrites is considered to be the enemy of the quarryman and constructor, since it decomposes with ease and stains and discolours the rock. Pyrites in sharp, well-defined crystals sometimes decomposes with great difficulty. If a crystal or grain of pyrites is embedded in soft, porous, light-coloured sandstones, its presence will certainly soon demonstrate itself by the black spot which will form about it in the porous stone, and will permanently disfigure and mar its beauty. If the same grain of pyrites is situated in or near very hard, compact, non-absorbent stone, the constituent minerals of which are not rifted or cracked, this grain of pyrites may decompose and the products be washed away, leaving the stone untarnished.

Seasoning Stone.

The thorough drying of a stone before, and the preservation of this dryness after, its insertion in masonry are commonly recognised as important factors of its durability; but the exact nature of the process of seasoning and of the composition of the quarry-sap removed by thorough drying have never been determined. The quarry water may contain little else than ordinary well water, or may be a solution more or less nearly saturated, at the ordinary temperature, with carbonate of calcium, silica, double salts of calcium and magnesium, &c. In the latter case, hardening results from the drying, and an exact knowledge of its nature might throw important light on the best means for the artificial preservation of stone. Again, water may exist in large quantity, in chemical combination, in the silicates (e.g. chlorite, kaolin, &c.) or in the hydrated iron oxides which constitute the cement of a building stone.

Unity in Architecture.

Simplicity and directness are cardinal virtues in all architectural arrangements. Avenues should be as straight, as short and as obvious in their course as possible. The rules for the moral conduct of a man are very applicable to this branch of our art; his ways should be clear and obvious, free from ambiguity and uncertainty, without tortuous or dark places. When a turn is necessary, let it be one which cannot be mistaken. There should be no seeking for the way in or out. The first impression on entering any building should be such as is becoming its special purpose. The temenos of a Greek temple was well calculated to give an impressive air of sanctity to the temple itself, by excluding from view all incongruous and mean objects, enhancing, too, the architectural effect of the façade by surrounding it with suitable accessories. A similar feeling, perhaps, led the early architects of Christendom to form that peculiar forecourt or atrium in front of the naos, of which but few examples now remain, although probably this atrium was an essential part of every early Christian church. The basilicas of San Ambrogio at Milan, and of St. Clemente at Rome, are very interesting and nearly complete examples. There can be little doubt that the builders of that devout age were influenced by subjective considerations of this kind, although the ritual appropriation of this portion of the building was to receive the catechumens of the Church, and to afford a suitable and becoming place wherein the candidates for baptism might present themselves. At all events, a very powerful effect must have been produced upon the eye and mind by thus shutting off from view the outer world, and concentrating attention on the more sacred structure about to be entered. It was, perhaps, a similar motive—a legitimate artifice for the purpose of strongly impressing the mind of the worshipper—that led our old church builders usually to form their doorways of very moderate dimensions. Great emphasis was ordinarily given to the western, and often to the lateral doors, by exterior decorations, and by recessed and gabled porches, often rising to a height of great grandeur; but the actual opening of the doorway will generally be found comparatively low. The natural effect of this is to produce, as it were, a surprise, and by the contrast to make more impressive the extent and loftiness of the structure within.

NOTES AND COMMENTS.

A REPORT has been presented to the Senate of the University of Cambridge by the Engineering Laboratory Syndicate. It states that the sum of 4,847*l.* 16*s.* has been raised by subscriptions towards the fund for the development of an engineering laboratory. In addition, several important contributions of apparatus have also been made. A part of the sum collected has been spent in providing apparatus for immediate use. About 4,100*l.* remains available for building or for the purchase of additional apparatus. The Syndicate recommend that plans drawn by Mr. MARSHALL for the engineering laboratory be approved, and that they be authorised to proceed at once with such portions of the work as they are able to execute with the funds at their disposal.

THE buildings of the Sorbonne, which are about to be demolished, are not entitled to be considered as extremely ancient. They were raised at the command of Cardinal RICHELIEU, and accordingly were used for over two centuries and a half. The first stone was laid in 1627. The Cardinal's buildings took the place of some which were old and dilapidated. The church of the Sorbonne, in which RICHELIEU's monument is to be seen, was built on the site of the College of Calvir, or "the little Sorbonne," which was demolished for that purpose, after surviving from the thirteenth century. It is strange that the Minister was insensible to the associations of a building that was founded by ROBERT DE SORBONNE as a preparatory school. There is nothing left which will connect the new Sorbonne with the old except the name and the educational principle which has been retained, although applied to a different sort of object. The aim of ROBERT DE SORBONNE was to afford instruction in theology gratuitously to poor students like himself at one time, and he wisely established his society at the foot of the hill of St. Geneviève, around which every experiment in education was welcomed. From 1253 until the suppression of the college at the Revolution, there were always at least six professors who held theological classes that were open to students without payment. Poverty was the badge of the institution. It was always *Pauperrima Domus*. The ablest doctors were, however, proud to aid in the teaching, and although the Sorbonne was only a part of the theological faculty of the University of Paris, it was accepted as being the most essential part. It was in the college the first printing press seen in Paris was set up.

A small sum of money was lately entrusted to the Boston Society of Architects to be expended in premiums for designs for the improvement of a part of the city known as Copley Square, in which buildings have been erected without any regard to general amenity. Twenty-two designs were submitted. The judges appointed were Professors WARE and CHANDLER, and Mr. E. M. WHEELWRIGHT, the city architect. They have assigned the first place to a design by Messrs. HARVARD, WALKER & KEMBALL, the second to Messrs. ROTCH & TILDEN's, the third to Messrs. ANDREWS, JACQUES & RAUTOU's, the fourth to Mr. H. L. WARREN's, and the fifth to Mr. W. G. PRESTON's. According to the judges the designs presented four essentially different methods of treatment. The first design shows a central area measuring about 270 feet square, occupied as a garden, with trees and seats, intersected by diagonal streets 50 feet wide. This treatment, it is said, has the three great advantages that it leaves the present line of Huntington avenue virtually unchanged (most of the other schemes contemplate a deviation of the avenue); that it affords shade and coolness at a point where they are specially to be desired; and that it offers a straightforward solution of the difficulties of the problem instead of endeavouring to evade them. Its merit, moreover, lies in the idea itself, and is quite independent of the way in which it is worked out. While it permits any amount of expense and richness in the shape of fountains, statues and other architectural embellishments, it requires for its satisfactory execution only a moderate expenditure of money. The second scheme shows a sunken area treated with steps and balustrades, seats and fountains. The architectural features do not compete in size or interest with the buildings by which it is surrounded. In the third

and fourth schemes the centre of the square has an octagonal or circular area decorated with seats and statues, the principal feature being a large monumental fountain in the axis of the Public Library and of the Museum of Fine Arts. In the four designs a fountain appears in the centre of the square, but in the fifth, as in many of the unsuccessful designs, a column or lofty monument is introduced which does not receive the approval of the judges. It is novel to find a society entrusted with the duty of selecting designs for a municipality, but at present there is no guarantee that the competition will lead to any transformation of the square except on paper.

IN spite of all that has been done in the production of rival manuals, "WEALE'S Rudimentary Series" retains its hold on another generation of students. What seems to be a new departure will increase its influence. Originally the volumes were written by men who had some claims to be taken as specialists, and although they professed to treat their subjects for beginners, it was inevitable that they should consider many circumstances as too elementary for notice. Archbishop WHATELY displayed his sagacity when he said that the best writers of treatises were men who had not exhausted their subjects. The success of WEALE'S series, or at least of many among them, we imagine has arisen from the number of a superior class of students who were competent to use them. But workmen have now to be considered, and those in the building trades would not be able to derive as much benefit from some volumes in the series as pupils in architects' and builders' offices. The volumes entitled "The Practical Plasterer," by Mr. WILFRED KEMP, plasterer, and "Roof Carpentry, Practical Lessons on the Framing of Wood Roofs," by Mr. G. COLLINGS, are different in character from preceding volumes in the series. The new treatises might be written by workmen for the use of apprentices, to whom everything they see done is strange, and consequently the pages can hardly be too elementary. The experiment has our fullest approval. Both writers appear to have read books to which they refer, but we prefer those parts where they speak from experience. There is no likelihood that such treatises will supersede those on similar subjects in the series; rather they will supplement them, and it may be help to introduce the older volumes to an extensive class of readers.

THE experiment of trying to discover meritorious pictures by means of voting does not appear to have been successful in New York. The circumstances were curious. A Mr. HALLGARTEN bequeathed money to the Academy of Design in order that three prizes of 300 dols., 200 dols. and 100 dols. might be annually given to painters of American origin, and under thirty-five years of age, who had produced the three pictures which in the opinion of exhibitors were best entitled to the rewards. As high prices are obtainable for inferior pictures in the States, painters do not need relief in the form of money, and during the past three years the prizes were disregarded. This year the value of them was therefore quadrupled, and some painters condescended to become candidates. There was a busy period of canvassing by the friends of the competitors. After some trials, the first prize was obtained by MORGAN MCILHENNEY, the second by Mr. E. A. BELL and the third by Mr. H. PRELLERTZ. The voters were not satisfied with what they had accomplished in the way of selection, for before leaving the gallery they besought the Council of the Academy of Design to seek for an alteration of the process by means of which the awards would henceforth be made by a jury.

M. FRANÇOIS ALEXIS CENDRIER, who died in Paris recently in his ninetieth year, was the architect of the Palais de l'Industrie in the Champs Elysées, which is used for Salon and other exhibitions. But he found his most profitable commissions in railway works. The stations on the Paris and Lyons line were designed by him, and some of the principal termini in Paris. His success was recognised in 1851 by his admission to the Legion of Honour. He was one of the foremost architects in France to utilise iron in his buildings, and generally he was ready to sacrifice tradition to necessity. M. CENDRIER was a pupil of LEBAS and PANDOVER, and was one of the holders of the Prix de Rome.

PARKER'S HOTEL, SURREY STREET, STRAND.*

THE revolution in the architectural appearance of some parts of London cannot be better exemplified than by a contrast between the old-fashioned private hotels and boarding-houses in streets off the Strand and hotels like the one we illustrate. Mrs. LIRRIPER herself would acknowledge that the change was an improvement. Parker's Hotel is undoubtedly as effective without as it is comfortable within, and it is one of those buildings we may often expect to see in the sketch-books of foreign architects.

THE TUNS HOTEL, ODIHAM.

THIS hotel has been rebuilt for Messrs. MAY & CO., Basingstoke, on the site of the old one destroyed by fire. It forms a picturesque feature in the main street. The contractor is Mr. J. HARRIS, of Basingstoke, and the architect Mr. GEO. W. WEBB, F.R.I.B.A., Market Place Chambers, Reading.

THE RICHMOND LOCK AND TIDAL WEIR.*

AFTER the removal of Old London Bridge the bed of the river became considerably lowered, but the effect of more water passing up and down with the tide was not felt until many years afterwards, on account of the numerous shoals between it and Westminster, when we have evidence that this increased scour caused the foundations of both old Westminster and Blackfriars Bridges to give way. More recently it has occasioned a large sum to be laid out in maintaining Waterloo Bridge, the foundations of which had become imperilled from the increased scour. Since 1862 very extensive dredging has been carried on both above and below London Bridge, so that further impediments to the flow of the tide have been removed, causing higher tides, whilst, on the other hand, few obstacles now remain to detain the ebb, which runs out very quickly, resulting in a reduced level at low-water.

The range of spring-tides at London Bridge in 1799 was about 15 feet, or 18 inches less than at Sheerness. Now the average maximum tides at London Bridge reach 21 feet, being nearly 5 feet more than at the mouth of the river. The oscillatory motion of the water travels up and down the river similarly to the swing of a pendulum, and although most of the increased range is due to elevation of surface, the water at London Bridge frequently recedes about a foot below the lowest sea-level.

Many people get the idea in their minds from witnessing the ebb and flow of the river that the tides are a fixed quantity which must be accommodated somewhere, otherwise the banks would be overflowed; but it is not so. The tide is simply energy from the mouth of the river in the form of a wave, which continues to exert itself until it meets with obstacles that deprive it of its momentum. The supply of water from the ocean is inexhaustible, and it must, therefore, be evident that if no water were permitted to pass, say, London Bridge, whilst the tide was coming in, the only result would be that so much less water would enter the mouth of the river.

The effect of the increased range of tide upon the neighbourhood of Richmond, it will be noticed, has been most remarkable. Before the removal of Old London Bridge the difference of level between the average high and low water at Richmond was comparatively small—only about 3 feet 6 inches. This afterwards became enormously increased, so that the difference now between the average height of spring-tides and low-water is over 10 feet. We have often high tides which rise 2 feet 8 inches above Trinity high-water mark; and on July 5, 1892, the lowest water ever recorded marked 11 feet below Trinity high-water, making an extreme difference in range of 13 feet 8 inches.

Memorials were first presented to the Thames Conservators from the inhabitants of the neighbourhood between Teddington and Brentford in 1860 and again in 1865, calling attention to the loss of water in the upper tidal reaches of the river. In June, 1871, a deputation waited upon the Board and complained of the lowness of the water and further deterioration in the condition of the river, urging the construction of a lock and weir in the neighbourhood of Brentford. After several months' consideration, the Conservators returned an answer that "they regarded as a most weighty objection to the scheme that it would exclude a very large quantity of tidal water, which at present exercises a most beneficial effect on the river below by the scour which it produces." The lowering of the low-water level, and the increase in the height of the tides, had been

gradually producing a changed effect upon the character of the banks of the river, which lost much of their beauty and picturesque effect. The extreme and continual alteration of the water-level ceased to produce the luxuriant growth of wild flowers, and the roots of the water plants no longer served to hold up the banks without camp sheathing or embankment.

Instead of the gentle, placid flow of the stream, which the fisherman and the lover of nature used to delight in, a rapid torrent began to take its place, which at some points in the river defied the utmost exertions of the expert oarsman. Water-lilies and weeds, which afforded cover for the fish, disappeared, and the scour of the tides brought up all the filth from the sewage outfalls below London, which, deposited on the foreshore, produced huge banks of mud where formerly it was almost as clean as the sea-beach.

The facts could not be refuted, and, in consequence of further representations, the Conservancy Board instructed the late Sir John Coode and Captain Calver to report to them whether, having regard to all the interests involved, it would be practicable and prudent for the Board to construct a lock near Brentford or Isleworth, and to advise the Board generally.

The result was a voluminous report, dated February 24, 1873, which, after reciting the facts and statements of the memorialists, admitted that "there is no doubt whatever that the comparatively pure water which formerly filled the upper reaches of the tidal Thames—say, from Kew to Twickenham—has been replaced by water charged with matter, more or less offensive, brought up by the spring tides, which in a state of comparative stillness has gradually dropped an offensive deposit upon the foreshores to, as far up as Twickenham, where it has remained and contaminated the air until the land-floods at the fall of the year have cleared it away again."

After dealing at considerable length with the tidal flow and its acceleration, which was regarded as an improvement to the river generally, it proceeded to argue that the river would silt up both below and above the weir, that it would cause tidal loss and injure the channel below it and that the navigation of the river would be impeded. It concluded with the recommendation that, instead of the construction of a lock at Sion Reach, which the late Mr. Leach, the engineer of the Conservancy, had estimated would cost between 25,000*l.* and 30,000*l.*, "That the river-bed be improved by dredging between Teddington Lock and Kew railway bridge to such an extent as will suffice to form as uniform a channel as possible, not less in any part than 100 feet wide at the bottom, with side slopes of four to one, the bed, within the limits named, having an inclination of 6 inches to the mile."

The estimated cost of the channel described was 34,500*l.*, and a plan accompanied the report, showing a further suggested general lowering of the low-water line, which, if carried out, would have involved the destruction of the two middle piers and three central arches of Richmond Bridge.

A copy of the report was furnished to the memorialists, with which they were very disappointed, but it does not appear that any plan accompanied it, and I do not think they realised at the time that a further lowering of the bed of the river was contemplated and that Richmond Bridge was in peril. When the agitation for the present lock works were in progress the Conservancy Board kindly allowed us to take a tracing of the plan.

As the Thames Conservancy were not in possession of funds to incur the vast outlay recommended for dredging a channel 100 feet wide, they proceeded to deepen the river in places where it was insufficient for navigation and form a narrower channel; but as soon as this was dredged the stream flowed into it, leaving larger foreshores exposed, and the natural dams of the river being partially cut through, the tide ebbed out quicker than before. When the river was deepened in one place the work seemed to be practically undone by dredging elsewhere.

In the meantime the memorialists had consulted Mr. Abernethy, who reported to them on June 5, 1873, that the best method of procuring an additional depth of water, particularly between Richmond Bridge and Teddington, and preventing the deposition of offensive mud on the shores and in the bed of the river was by the construction of a lock and weir.

As the depth of water continued to diminish from year to year, so dissatisfaction on the part of the riparian owners and those using the river became more pronounced, and on October 13, 1883, a public conference of the inhabitants of the neighbourhood took place at the Castle Hotel, Richmond. Several resolutions were passed, and amongst them the following:—"That the various attempts which have been made to improve the state of the river by dredging have not only failed, but made the condition of the river worse than before."

A committee was appointed with the Earl of Kilmorey as chairman, a subscription list opened and over 1,000*l.* quickly subscribed towards the expense of promoting a Bill in Parliament.

The result was a report and plan of a proposed weir and locks at Isleworth, put by Mr. Abernethy, and notice was given by the promoters, through their solicitors, Messrs. Bircham &

* From a paper by Mr. J. B. Hilditch, read at a meeting of the Society of Arts on the 10th inst. and published in the *Journal*.

Co., of their intention to bring in a Bill in the approaching session. Mr. Charles Burt, now mayor of Richmond, and our chairman this evening, made every effort to induce the Thames Conservancy to consider the scheme favourably and avoid a Parliamentary struggle, but it was to no purpose. They viewed the question chiefly in the light of the maintenance of the navigation, and could only support measures which were for the benefit of the river as a whole. It having been reported to them by eminent engineers that the vast interests of the port of London might be imperilled by the construction of any permanent weir or dam, it followed that the erection of such a work would be resisted.

When they were approached the answer returned was that they were willing and anxious to ameliorate the condition of things complained of as far as lay in their power, but they could not sanction one portion of the river being restored to the detriment of more important interests, and that the proper course of treatment to pursue in improving the river was by further dredging.

In the end they submitted certain plans, giving four sections of the river at different spots between Teddington and Richmond, and offered, on condition that the notice of the Bill was withdrawn, to spend a large sum of money in improving the river between Isleworth and Teddington Lock, by removing the shoals and mud, securing the banks with stone facings, &c.

A considerable portion of the amount subscribed was consumed in preliminary expenses, and the committee, having in view the large sum that would necessarily be expended in a Parliamentary contest, had no alternative open to them but to withdraw the Bill, and allow the Conservancy to proceed with their treatment of the river.

Although far from satisfied, some members thought they had succeeded in wresting some valuable concessions from the Board, which, if not all that was desired, at least held out the promise of some reward for their labours.

In this, however, they were greatly disappointed, for matters only continued to get worse. When a further loss of water was first noticed it was attributed to the dry season, and it was said that when a larger instalment of the scheme was carried out, depth of water would be obtained.

However, nothing of the kind took place; boats and barges kept grounding, and within a few weeks of the dredger being set to work between Rainshead and Isleworth ferries, the low-water level dropped nearly another foot. A considerable fall of water through the arch of Richmond Bridge now appeared, so that it was most difficult for any but an expert oarsman to row through the arches, and this state of things has continued ever since.

Mr. Abernethy's scheme first set me thinking about a half-tidal lock and weir, and, looking over some old newspaper cuttings, I find I suggested, in a letter to the local paper in October 1883, a weir which, whilst holding up the water, should allow the stream to pass on the level of the bed of the river, and only be operative during the period of low-water, and this is exactly what the Richmond sluices are designed to effect.

In consequence of my having called the attention of the Richmond Vestry to the diminishing level of the water and exposure of the foreshores, as a consequence of attempting to carry out the further dredging of a channel in the bed of a river, which seemed to threaten most serious results to all concerned if further proceeded with, a number of gentlemen, who had supported Mr. Abernethy's scheme, met at my house on July 18, 1884, to consider what had best be done.

Although these proceedings were complained of, and termed irregular by the Conservancy Board, who continued to prosecute the works they had undertaken, and ultimately spent 23,500*l.* upon them, it really proved the initiative step to a reversal of the policy pursued so many years to the detriment of the neighbourhood.

Up to this time a somewhat jealous feeling had existed between the Twickenham Local Board and the Richmond Vestry. Twickenham had on more than one occasion acted independently, but now the extreme sufferings of both called forth a determination to work together. The condition of the river then had become so desperate that the channel between the town and the large flat, known as Eel Pie Island, dried up at low-water. The watermen could not get to their boats, and to call attention to their miserable plight, took to playing a game of cricket one afternoon in the bed of the river.

The various appeals to the Thames Conservancy were always very courteously but firmly replied to, and held out no hope whatever of the state of things, which became very bad in the summer of 1884, being ameliorated.

About this time a joint committee, consisting of six members of the Twickenham Local Board and six of the Richmond Vestry, was appointed to confer together and endeavour to bring pressure to bear upon the authorities.

A Royal Commission was suggested, but this, it was found, would be most difficult to obtain for such a small section as three or four miles of the river. An appeal was made to the

Board of Trade, and eventually in 1888 it was arranged that an inquiry should take place before an arbitrator. In order to meet expenses another appeal was successfully made by Mr. Charles Burt, the chairman of the Richmond Vestry, and Mr. Charles Thrupp, chairman of the Twickenham Local Board, who, together with myself as chairman of the joint committee, composed an executive committee, and the campaign was opened.

Mr. Wolfe Barry, M.Inst.C.E., was appointed, and the evidence being prepared to lay before him, when the whole scheme collapsed owing to a stipulation being made that before proceedings were commenced the complainants should deposit 1,500*l.* to guarantee their portion of the cost of the inquiry.

This sum being so much more than was anticipated, and there being no certainty that if the promoters obtained a decision in their favour any immediate relief would follow, the idea had to be abandoned, and attention was again given to the promotion of a Bill in Parliament, which it was thought, even if more costly, would carry with it definite powers to construct works for relief. To proceed on these lines with any chance of success, it was first of all necessary to provide a scheme that would command the confidence and support of able engineers.

All this time I had been studying and making notes of the condition of the river and I had taken many photographs, showing the extent to which the bed of the river was exposed at low water.

Being convinced in my own mind of the strength of some of the arguments used in opposition to the erection of an ordinary fixed weir of solid construction, I turned my attention to movable ones, and, in the autumn of 1877, examined several of the Continental systems on the Seine, the Yonne and the Marne. I returned very much impressed with the magnitude and importance of these works, and feeling that we were very much behindhand in schemes for impounding water at home. At the same time the conditions and objects aimed at were quite different. Being above tidal influence they were all designed to maintain a navigable depth of water in dry seasons and prevent flooding in wet ones, and only required erecting and removing when these changes occurred; whereas, in the case of the Thames at Richmond, a change of level took place with the tide twice in twenty-four hours.

In most cases the erection of the dams (or barrages, as they are called) is slow and tedious, and their removal almost equally so. To provide for the rise of the tide it was absolutely necessary to have some scheme that could be completely and readily manipulated in the shortest possible time.

The needle weir and the chanoine wicket, the most largely adopted systems, were exceedingly slow in removal.

The curtain-dam of M. Camère, at Poses, on the Seine, which is considered a magnificent work of its kind and was holding up 13 feet 6 inches of water when I was there, did not possess features that could be readily adopted. The curtains, which somewhat resemble wooden revolving shutters, occupied fifteen minutes in rolling up, and the iron frames upon which they worked, suspended from a footbridge above, took twenty minutes in raising and ten minutes in lowering.

The hydraulic weir of M. Girard and the drum weir of M. Defontaine were the only ones that met the requirement of speedy removal successfully, but they were both expensive systems. I was much struck with the latter, which consists of a succession of balanced paddles, the lower halves being recessed into the bed of the river. By turning a valve the head of water maintained causes the paddles to lie flat on the bed of the river, and the weir disappears. When in operation the evenness of the fall of water was very perfect, almost resembling a glass shade, and looking down the river one witnessed the curious effect of two different levels of water, without any apparent cause. The objection to this system was that with tidal action deposit might take place in the drum and stop its working effectually, and it seemed to me very objectionable to have working parts in the bed of the river, where they were difficult of access.

More than one adaptation of these schemes had to be laid aside with disappointment, and a plan of tidal gates, after occupying much thought and consideration, at length gave place to Mr. Stoney's sluices. The drawings of these interested me very much from the first, but there was no example to be seen in England. It happened that Mr. Stoney had been occupied in obtaining a prolongation of his patent, and a friend of mine, who had advised him, introduced me to him and also to Messrs. Ransomes & Rapier, of Ipswich, who were interested in working the invention.

About this time the Manchester Ship Canal scheme was making progress, and the conditions met with here more closely resembled those of the Thames at Richmond, on account of the lower portion of the canal being subject to tidal influence. Mr. Stoney's sluices were entertained for regulating the control and discharge of the river Weaver. Mr. Leader Williams and other engineers were about to visit Ireland, where the nearest examples could be seen in operation, and I was invited to join the party. We first visited Ballinasloe, county Galway, and

afterwards proceeded to view larger sluices, of 30 feet span, at Belleek, county Sligo. One could not be otherwise than impressed with the facility with which huge gates of this width, 14 feet in depth and bearing a static pressure of 85 tons—due to the head of water maintained—were readily moved by hand; but, of course, what was visible above the water-line of such a solid erection had not the most pleasing appearance, and was not of a nature that we could propose to introduce into the residential neighbourhood of Richmond.

As a bridge was not required, and would probably have been opposed at the sites that had always been considered the most suitable for the erection of a lock and weir of the usual type, the cost of the footbridge necessary for the working of Mr. Stoney's sluices was one of the objections to the scheme, and remained so for some time. At last, one day it came into my mind that if we had the courage to adopt the present site for the scheme, the bridge would be of great service in affording improved communication with Isleworth and St. Margaret's, where only ferries existed, and there being a highway on the Middlesex side, the objections of the landowners would not be encountered, and no compensation demanded. Moreover, the river here was broad and its course straight, which the scheme required on account of the scour of the sluices when shut, and the passage of the river traffic when open.

After making these suggestions to Mr. Burt and Mr. Thrupp a meeting of the committee and several engineers again took place at my house, to view the site and decide upon a scheme. The difficulty that remained was the unsightliness of the sluices when not in use. I had suggested turning them over, and lowering them into a recess in the bed of the river, to which, however, there were objections, when a member of the committee asked if they could not be turned up instead. To this Mr. Stoney replied that he had thought of a plan which would enable him to tuck them up under the arches of the bridge, so that they would be out of sight. His suggestion and method of carrying it out met with the approval of all present, and before the meeting terminated the problem was considered solved. With his ready resource Mr. Stoney overcame difficulty after difficulty as they presented themselves, and soon produced a very practical scheme, of which an excellent working model was made.

I shall not be able to dwell at length on the Parliamentary proceedings, which, under the skilful guidance of Mr. Charles Burt, who I have personally to thank for presiding here this evening, were admirably carried through to a successful issue. Only those connected with the promotion of the scheme know the amount of energy, labour and thought he brought to bear upon the subject, and there can be no doubt that to his ability and knowledge of Parliamentary procedure was due the passing of the Bill. There were no less than fifteen petitions lodged against the Bill in the House of Commons, and the evidence was so voluminous that it occupied ten days, whilst there were nine petitions against it in the House of Lords, which took up the best part of six days.

I ought to mention that Mr. Thrupp suggested that the local authorities should be made the promoters of the Bill, and the consent of the ratepayers having been obtained, under the Borough Funds Act, in Richmond by an overwhelming majority, and in Twickenham by a very substantial majority, the Bill went forward with the full sanction of these parishes.

The Heston and Isleworth Local Board held a meeting for the purpose of opposing the Bill with the ratepayers' money, because Isleworth was disappointed that the site selected was situated above the town; but the vote of the residents of St. Margaret's, a small portion of the district benefited, was solid enough to decide the question in favour of the scheme. The estimated cost of the works was 40,000*l.*, and this sum was fixed by the Act to be contributed by the districts rated.

As soon as the Royal Assent was obtained on August 14, 1890, the Thames Conservancy Board met to consider the provisions of the Act, which provided that, if they were unwilling to accept the construction of the works themselves within a period of six months, the local authorities would become empowered to undertake them. Within the time specified they intimated their acceptance of the responsibility, and proceeded to purchase plant and make provision for the construction of the works.

Mr. More, the engineer of the Conservancy Board, promptly took in hand the working drawings, and suggested improvements in the design of the footbridge and an enlargement of the lock, which considerably enhanced the estimated cost of the work. It took a considerable time to erect landing stages, cranes, &c., the first pile being driven on July 1, 1891. The concrete foundation of the first pier was put in on March 25, 1892, and the works have proceeded steadily ever since under the able superintendence of Mr. Le Neve Foster, the engineer in charge.

The abutments and piers of the bridge are built of Staffordshire blue bricks faced with Cornish granite. The lock is to be 250 feet long and the gates give a clear opening of 26 feet, but to accommodate a tug and full complement of barges the lock widens out on the shore side to 37 feet for about two-

thirds of its length. The work in this section is from five-eighths to three-fourths finished.

The whole of the bed of the river is laid bare in sections between the foundations of the piers by means of half-tide coffer-dams, which have to be pumped out for each day's working. A wide and deep concrete apron is formed between the rows of sheet piling on either side, which are driven deep down into the bed of the river, and in the centre is laid a granite sill, on which the sluices would rest if they were let down to their fullest extent; but, as I shall presently explain, they are suspended by counterbalance weights, and kept floating by the head of water, maintained just sufficiently to allow all the stream that comes over Teddington Weir to pass underneath. When first brought before the Committee of the House of Commons, the design of the bridge had seven arches of 40 feet span, five of which were to be fitted with sluices, whilst the side arch on the Middlesex side was to be fitted with rollers, as a slipway for pleasure-boats, and the lock built under the arch on the Surrey side.

The largest sluices that had been made were 30 feet span, and Mr. Stoney was afraid to propose a much wider span in case he might be thought to be too bold, although fully convinced in his own mind how much simpler the scheme would be with fewer spans.

Opposition evidence having been brought to show that it was now the modern course of engineering to increase the spans of bridges as much as possible, Mr. Stoney at once offered to increase the width of the sluices, and reduce the number of spans over the stream to three, and the plans were so altered when taken before the House of Lords.

I will now describe the mechanical part of the structure, which has been constructed at Messrs. Ransomes & Rapier's works, Ipswich, where the sluices for the Manchester Ship Canal were also made.

The three spans over the river are actually 66 feet wide, the side arches over the lock and slipway 50 feet each, and the clear headway under each is 1 foot more than at the Richmond railway bridge.

The sluices which fill the spans are made entirely of steel, with the exception of the end-bearings and the trunnions upon which they turn from the vertical to the horizontal position when raised out of sight. The sluices are 12 feet deep, and each weighs 32 tons, being suspended at each end by four steel-wire ropes 1 inch in diameter. The steel-wire ropes pass over pulleys attached to the lifting-gear, and to the other ends of these are attached the counterbalance weights. There are four, of 8 tons each, suspended in 3 feet square wells made of steel plates built in the masonry, and recessed one on either side of the end of each sluice, two wire ropes being connected to each. The steel wells also serve to support the guides and bearers, which are planed surfaces of cast-iron, between which and the bearers of the sluice are interposed Mr. Stoney's patent rollers, which will receive the static pressure of the water when it is impounded. There is a set provided on either side, so that no matter whether the stream is flowing up or down the friction from the pressure which would otherwise result is almost entirely eliminated. The rollers are suspended independently with counterbalance weights of their own, and travel slower than the sluice, having less distance to cover, and are always ready to take the strain when the sluice descends to the point at which they stop.

The counterbalancing of the sluices is so perfectly adjusted that the buoyancy of a balk of timber running along the top of the up-river side of each sluice is sufficient to float it, and cause it to ascend with the rising of the tide. When the scheme is in operation, it will regulate automatically the flow of the stream under the sluices at low water, and maintain a nearly fixed level after the period of half-tide is reached and the sluices have been lowered. In addition to the large counter-balance weights there is a link-chain arrangement on either side carrying small weights, which provides for the adjustment and difference in weight of the sluice in and out of the water and according to the extent to which it is submerged. The turning of the sluice from its vertical to the horizontal position is accomplished by means of a wrought-iron arm projecting from one end of the sluice carrying a small pulley, which travels in a curved guide on the upper side of the pier of the bridge.

The lifting gear is similar on either side, motion being imparted to the pulleys over which the suspending wire ropes pass in the usual manner. The windlass is only attached to one set of gear, and, in order that they should work quite simultaneously, the power is conveyed by means of a 5-inch shaft and spur gearing from one side of the arch to the other.

On the land pier of the bridge, on the Surrey side, accommodation will be provided for the lock-keeper and his assistants, and similar rooms will be built for the toll-collector on the other side, near the slipway. Being arranged under the staircases leading to the foot-bridge, they will not be much seen, and have rather a good effect in giving solidity to the land arches.

The Act provides that the sluices shall be worked so as to hold up the water of the river above the bridge to as nearly as may be 5 feet 9 inches below Trinity high-water mark.

The sluice usually occupies about three minutes in lifting when worked by two men, but it can be done in much less time with quick gear, and it is very interesting to see such a huge mass of metal (probably the largest in bulk if not the heaviest that has ever been lifted in a similar manner) gradually rise out of the water in which it was previously suspended floating, and after closing the 66-feet opening of the arch, and eclipsing the view of the landscape for a time, disappear above the arch, leaving the river as free as if it only were spanned by an ordinary bridge.

VALUATION OF PROPERTY.*

IN this paper I do not propose to deal in any way with such valuations as those of large estates, land allotments or valuations made for rating purposes, but solely with those which an architect's practice brings him in contact with, such as residential or business premises, whether for personal use, for investment, for mortgage, for the settlement of disputed accounts, for progress certificates, for building society work or for dilapidations. All require a somewhat long practical and perhaps tedious apprenticeship, with a good deal of common-sense judgment thrown in. It is to be regretted that the practice of employing a competent architect to inspect, report upon and value premises before purchase is of such rare occurrence, for I am certain it would be the means of saving much after dissatisfaction, and many vain regrets were this the rule and not the exception. How often do we hear a client say, "I have purchased such and such a house or property, and I want you to come down and look at it." Then, when the practised eye discovers this and that defect, which requires often immediate remedy, and finds that a good deal of money has yet to be laid out to make things satisfactory, there is grumbling and irritability and it is almost invariably an unpleasant job. The first thing to be thought of is the suitability of the site for the class of building, whether for personal residence or for letting purposes. A residence quite proper for one district would be quite out of place and of far less value in another, though the actual cost may have been the same. Next as to its sanitary suitability, and this in new suburbs is a serious matter—whether it is liable to be annoyed, and not only annoyed, but injured by a neighbour's or prospective neighbour's drainage, and also if its own drainage can be satisfactorily disposed of. The building then as a structure must be carefully examined, noting those defects that are only of a temporary nature and making an item of the cost of reinstating. Look carefully for any signs of damp, not only internally but externally, for I have known houses patched up for sale as artfully as a spavined, broken-winded horse for the yards; neat little dados hiding the bulged and blackened paper, plenty of stain and varnish used, portions of the rotten floors removed, and any amount of tricks to salve over for the time the sore beneath. If signs of dampness are found no trouble should be spared to find its cause. It may only be caused by some easily remedied defect, or as is most often the case, by inherent bad construction, bad bricks or want of a damp-course. Then of course would have to be taken into account the probable cost of the remedy, which as a rule would in the case of small properties stop the transaction and save your client worry, time and money. The age of the building must be taken into consideration and an allowance made for depreciation. In this matter judgment forms a large item, for take a dozen properties of the same class and age, they will all differ to a certain extent, according to the care which has been taken of them by their respective tenants or owners. This is particularly the case in wood buildings, as being so much more liable to injury and decay and whose term of life is short. Now measure the building and price it as new according to its class, and make the deductions as before mentioned. The land value must be then added, of which I will speak more particularly when touching upon building society work.

The same routine should be gone through for purchase as for investment, care being taken to remember to deduct from the rental value those many incidentals which mount up to a considerable item, such as percentage for collection, rates, insurance, unexpected demands by local boards, the eccentricities of the Board of Health, the sewerage and water rates if in the metropolis, the cost of roads and right of ways in suburbs if not taken over by the council, and periodical painting, repairs, &c. Do not be led away by what a place may be let for. Rents in the past have been far too high, and it was only a matter of time when they would in the natural course of events come down; but again a great deal of property is at the present time either unlet or let at rentals which are most inadequate to

the cost—cottages at 1s. per week, and residences dropped from 150l. per annum to 70l. and 80l. cannot be said to be fair criterions, and again the practical judgment of the valuer must come in. A class of property which is very unstable is one that has been created by some factory, more especially if in suburbs or away from town, for in case of the failure of the works the population, having nothing to fall back upon, migrate to some other spot, the houses being left tenantless. This can be seen clearly illustrated at the present time by a look round any of our outside and formerly busy brickworks.

In inspecting for mortgage, especially for short terms, so much minuteness is not necessary, but the main points have to be quite as carefully studied, for in most cases the moneys lent upon mortgage are either trust moneys or practically so. Again, I would impress the care to be exercised in dealing with the rentals. They are frequently put up for the purpose of mortgage and the tenants allowed a drawback. I have known this done by people who would be grossly insulted if called swindlers, but it is certainly sailing very close to the wind. A point in mortgage matters which is very frequent at home, but very seldom comes into calculation here, is in connection with leasehold properties. As the practice of granting building leases is increasing in Australia, and will increase in greater proportion in time, I may as well mention it, *i.e.* the length of the remainder of the lease. A careful mortgagee will call in his mortgage on leasehold property on the remainder reaching between twenty-five and twenty years, *i.e.* by the "remainder" I mean the length of time the lease has to run before it terminates, and this shows the absurdity of building leases of thirty or forty years only if anything like substantial building is required. One year's peppercorn and 99 years' lease is the usual at home, the City of London Corporation giving eighty years. In large city buildings used for office purposes great care and discrimination must be used, as it is most usual for money to be borrowed for these on the assumed rentals marked on the plans before the building is erected, and I leave it to you to imagine the position of a mortgagee at the present time lending up to three-fourths on the values put on a block of offices five years ago. Warehouse and factory property must have taken into account its risk of fire and damage in accordance with what it is used for. And all properties must have the question of fire seen to.

The way in which building society work has to be done is to my mind the most unsatisfactory of any. A so-called plan and specification are sent to the surveyor with a sketch of the position of the land and the form of application. The plans are, as a rule, rough attempts by a mechanic without any knowledge of drawing; in many cases are only in pencil, worked off with a 2-foot rule, indicating neither construction nor detail. The specification merely enlightens him whether it is intended to build in brick or wood, with just a few general clauses, seemingly remembered from hearing some specification read, but with no detail. From this unsatisfactory basis you have to state the value of the building when erected. Then you proceed to identify the ground, and on the "boom" estates this was often a matter of some difficulty, as auctioneers seem to have the most peculiar ideas with respect to distances from railway stations. When the estate was at last reached a plough track through a paddock was the only indication of "The Grand Avenue," "Hopetoun Parade," or some equally pretentious name. However, the block adjoining had sold for 8l. a foot, the next at 9l., &c.; and as your instructions are the present price, down it must go at 7l. or 8l. You must not use your judgment, and say "this is not the class of house for such priced land" or "the price is absurd;" nor are you called in to advise the directors in the matter, but simply to put the plan of position of property upon the form, to fill in the present price of the land and the presumed cost of the house, to get your fee, which as a rule is most inadequate, and then the first performance is over. You may not come upon the scene again; if you do, it is for the progress payments. Here you are handicapped again, for you have nothing to tell you if this man is carrying out what he proposed to do with the society, and you must value what he has done and just send in a memorandum of the amount. If you do your duty here, there is no end of grumbling to put up with and often abuse. In progress payments of this description, even greater care should be exercised than in those of proper contracts for buildings, for you have no hold on your man; as a rule he is a jerry speculating builder, and also as a rule the society have agreed to lend him more than they ought, and the sooner he can get hold of the money the better for him. He tells you pretty straight the amount he expects, and I regret to say we have generally differed on the subject. The advances should be kept very low until the building is covered in and protected, the gutters and down pipes fixed, and generally in such a state that should circumstances arise preventing the completion for a time the structure would not be damaged. Always bear in mind to keep a good margin back to be able to complete, if so compelled, without loss, and not losing sight of the fact also that all fees, legal charges and the society charges, interest

* A paper read before the Victorian Architectural and Engineering Association by Mr. G. V. Blackburne, and published in the *Australasian Builder*.

and often fines have to be thought of in this class of work. I am perfectly certain that had our building societies insisted on proper plans and specifications and employed proper surveyors who knew some of the troubles of this kind of work, and especially had they let them have copies of the drawings of all works to be inspected, they would, instead of being, as they are now, in a state of either insolvency or collapse, have been flourishing and doing good work. There is also just one more point before I leave the building society. My experience has been that an honest, straight man, who requires the aid of a building society in its presumably legitimate business, either gets no reasonable offer or has no end of worries and obstacles placed in his way, while the speculator has not the slightest difficulty, and sails away to his haven of rest, often leaving the society with a white elephant at the finish. In progress certificates in contract work the routine is much the same, but while there are not the same contingencies to provide for, others often crop up. For instance, though it may seem a little bit hard to say that if a contract is taken very low, less money than usual should be certified at first and even afterwards, an extra margin should be seen in case your job should happen to be the last straw and you are left in that most unpleasant of positions of having an unfinished building on hand. In large buildings, as a rule, you have the quantities to go by. These, of course, are an immense help and safeguard, but here again is a little dodge to be watched, for they are often so priced as to procure for the contractor a far larger proportion of the earlier works than on the values of the finishing trades. I may seem to have insinuated some rather hard things about contractors, but where I am pointing out warnings to my younger brethren, it is not in respect to the honourable and straightforward contractors, of whom I am glad to say my experience has been that they compose the large majority, but it is also my experience in about twenty-five years of hard and varied work that there are some who certainly cannot be classed among those. It is therefore necessary to know how one might be got at in case of having the misfortune to be associated with one of the latter description.

The first certificate should never be given until you are perfectly satisfied as to the thorough completeness of the works and all accounts have been properly adjusted. Though you may be protected by the maintenance clause, it is always an unpleasant and unsatisfactory matter for all parties if the buildings have to be entered upon again for the purpose of putting something right. It often happens that the proper adjustment of accounts is not such a simple matter, and a great difference of opinion is frequently found between the interested parties, leading as a rule to law. It is simply astounding the way in which people rush off to their lawyer with technical accounts, more especially in connection with buildings, wasting time, money and temper on lawyers and barristers, who make the most awful jumbles of the matter if not properly coached by an architect, and which would be amusing were it not for the disastrous and often unfair results. If referred to some known practical architect, the whole thing could be settled for a twentieth part of the cost, and certainly on a reasonable basis. Should you be placed in the position of an arbitrator in a matter of disputed work and accounts, always, if possible, go and see the work yourself. Do not be satisfied with the mere evidence. Take a cupboard front, for instance. One side says it is only a cupboard front, just panelled and moulded, and of such a size. That sounds simple enough. The other side admits the size, and to a certain extent the description, but says the mouldings were peculiar, entailing more labour, &c. The thing sounds nothing on the face of it; but perhaps if you see it you will find the panels are odd shapes, the mouldings special-struck or handworked, and generally the whole quite out of the common, and the contractor has really only charged a fair price. This is a very simple illustration, which could be expanded *ad lib.* It is once more the practice and experience that has to be brought to bear in valuing for fair prices, for the reading of the specification will often here come into account as to how far the contractor should reasonably have understood the amount of work required, or how deficient the architect has been in properly expressing his meanings. Specifications are not always perfect.

Valuing for dilapidations is not a matter which troubles us much here at present, but, like the leaseholds, will come in time, though I do not suppose even the youngest of our members will have the same experience as myself once in London, where I made a survey on the expiration of a 300 years' lease. The work of arriving at values of dilapidations has been the source of endless litigation, the practical part of the architect being so hedged about with the technicalities of the law. The age of the building, the length of the lease, the state on entry, the question as to what is "ordinary wear and tear" and a hundred and one quibbles and points meet the surveyor. But I am glad to say light is now rapidly getting let into this heretofore fearfully complex matter, and some of the judges have lately very clearly placed the law before us. Blackstone defines waste as "spoil or destruction to houses,

gardens or trees or other corporeal hereditaments, to the injury of the reversion or inheritance." And waste may be taken under two heads, viz. "commissive" or "permissive," and the terms speak for themselves, commissive being injury personally done by the tenant or others, and permissive injury permitted to be done by neglect, such as allowing a leak to continue to the injury of the premises or such like. Grady also is an authority on this subject. There should always be a proper schedule and report drawn up by a surveyor as to the state of premises at the time of a tenant's entry. This would save a great deal of the unpleasantness often engendered at the termination of a lease. The great question of "tenantable repair" was fought out in the case *Crawford v. Newton*, when Mr. Justice Cave gave judgment in respect to the dilapidations, and very clearly laid down the works which could and those which could not reasonably be required. This case was appealed against, and the Master of the Rolls upheld and confirmed the learned judge's definitions—that a tenant was not liable to paper and paint, and leave the house in the same condition as when he took it, and took exception to the following articles in the schedule:—Wash, prepare and distemper ceilings and cornices, strip walls, stop, prepare and repaper, prepare and paint woodwork three coats. The Master of the Rolls held this was "decorative" not "tenantable" work. Mr. Justice Cave again, in the case of *Proudfoot v. Hart*, in the Divisional Court, after the referee had stated that papering, &c., had to be done again, clearly laid down the difference between "ordinary wear and tear" and permissive damage, especially in regard to a floor, which was one of the subjects of the dispute. Here, he said, the tenant was bound to repair as long as repair was possible; but when it got to such a state that patching up was no good, the tenant could not be called upon to put up a new one. He also, again, but more minutely, went over the other repairs, with the same views as given in the former case. This case was taken to the Court of Appeal, and Lord Esher practically confirmed the finding of the Court below, but would also give discretion; for he here says in respect to dilapidations almost precisely what I have said before in this paper as to value of residences, *i.e.* what would be quite right and proper for Grosvenor Square would be out of place in Spitalfields. Take Toorak and Collingwood in lieu of the other names, and you have a simile. There are still many points which have not been cleared up, because so much depends on the wording of the maintenance clauses of a lease. Great disputes are constantly occurring in reference to drainage when called upon by some local body to alter or redrain, also as to the making of roads and footpaths; but the authorities go to prove that the tenant cannot be charged with these items. In this paper I have tried to give our younger members some idea of the proper lines to work upon in the different class of valuing work that comes within the scope of our professions. The detail of making up these valuations depends so greatly on circumstances surrounding the different cases that it would scarcely come within the scope of this paper. To my older brethren I am afraid I have been tedious, as so much of it must be all stale news to them, but still I hope I may have been able to touch upon some point that has even interested them.

CONSTRUCTIONAL WORK IN IRON AND STEEL.

THERE are so many trade catalogues which are put together without discrimination it is no wonder the majority of architects treat all examples of that class of production with indifference. The first step in preparing a catalogue should be to consider what architects really wish to know about the particular class of goods, and in the next place efforts should be made to supply that information in a trustworthy form. Messrs. Moreland & Son, of Old Street, E.C., have just issued a catalogue (we suppose we must apply that name to it) which is a model of what is required. The pages make no attempt to be exhaustive of all that is done in their workshops, or is visible in their warehouses. That would be too onerous a study, however useful it might be made. Messrs. Moreland & Son simply present a few types of the structures they have carried out (and which are more suggestive of what is feasible than the speculations in many books on construction) with some results of their own tests on steel columns and stanchions, English rivetted steel girders, rolled steel joists, steel channel girders, &c. It will be said by those who take only a superficial glance at the pages that rows of figures and sections of girders and rolled joists have already appeared in wearisome iteration. Indeed, it requires no great theoretical or practical knowledge to work out such "information." What Messrs. Moreland & Son furnish is of a different kind. They do not say these forms exemplify the utmost that can be done in girder-making, or here are the weights which such a section of beam should sustain. All they claim is that they have produced girders which were required to meet novel difficulties

and that their girders have answered the requirements efficiently. The beams and joists could no doubt be proved to be capable of sustaining greater loads than are recorded. Messrs. Moreland & Son merely put on record the safe loads which they can guarantee. There is no puff; figures and diagrams unaided have to become convincing to the initiated. This plan may be unusual, but it should be remembered that Messrs. Moreland & Son are not agents but engineers. As they believe in the eloquence of sound construction, it is natural they should assume that architects and builders would look at things in a similar aspect.

We refer the reader to the tables for information about loads on girders and joists of various sections. It will be evident from them that there is economy to an important extent in the use of steel girders.

The examples of construction in steel are varied, and all are interesting. A very light and graceful dome, 36 feet span, at St. Joseph's Church, Highgate, is made of light steel ribs, abutting against a steel ring at apex, and at base bolted to brickwork. The covering is of copper plates. It is effective, and imposes only compression on the walls. There are several roofs. One, in the hall of the Mark Masons, Little Queen Street, has a clear span of 41 feet 9 inches. The form was determined by the necessity of non-interference with ancient lights and a respect for a ceiling, and had to be kept low. Strains on the walls are avoided by resting the principals on slight ribs, which are brought down just below floor line, and are tied by the girders which carry the floor. This is an ingenious arrangement, and from the absence of cumbrous forms it is well adapted to meet many difficulties in connection with town buildings. Truss girders up to 60 feet span, to carry superstructures, are next introduced. A roof is shown which is in the Battersea Town Hall. The span is 56 feet. The principals, which are 11 feet apart, are light, and the tie-rods correspond with the curve of the ceiling. The polygonal roof for Hengler's Circus consists of sixteen trusses, meeting as a centre-piece at a ventilator 6 feet diameter, constructed of steel plates, which serves as an abutment, and also carries the sun-burner. The curved principals of the Newport Market, which are 60 feet span, are carried to the ground, and the use of columns is avoided. In that, as in several other cases, the roofs can be erected without the aid of scaffolding. Examples of Mansard roofs, trusses with joists for floor serving as tie-beams, and simple roofs are given.

Another division of the catalogue exemplifies fireproof doors and shutters, as well as steel flooring formed of trough-girders, which is especially well adapted for carrying pipes, &c., for heating, ventilation and lighting. Altogether the catalogue of Messrs. Moreland & Son has merits enough to justify its preservation, and it will be found a very suggestive guide to every one who is concerned in the employment of steel or iron, in columns, stanchions, girders, roofing and flooring.

THE GREY FRIARS' CHURCH, CARDIFF.

ALTHOUGH it is the fashion to call Cardiff a modern town, says the *Western Mail*, its history, military and ecclesiastical, is ancient. The first syllable of the name takes us infallibly back to pre-Roman times, and there is evidence that when the conquering legions fought their way to Cardiff they found it a fairly considerable centre. Laying through its midst one of their grand roads, they passed away, and by-and-by other conquerors came and reared a grim castle, whose halls must have echoed with many a Norman jest, and whose dungeons bore witness to the moans of those whose greatest crime was fidelity to Fatherland. With the building of the castle came men carrying the cross—holy men who went about doing good, and who built fair churches and religious houses and endeared themselves to the people, and kept alive in olden Cardiff the flickering flame of religion. Years passed, disaster and decay told their inevitable tale, and the spoliations of a certain Henry, the eighth of his line, completed the havoc. The religious houses vanished, St. Mary's—that fair edifice—followed, and only St. John remains, sharing with the castle the burden of years, and telling to the busy denizens of to-day the strange story of the silent past.

Some such reflections as these passed through the mind of one of our representatives, who, acting upon information which had reached us, sought and fell into conversation with Mr. Fowler (of Messrs. Kempson & Fowler), a gentleman who has been conducting archæological investigations for some time under the direction of the Marquis of Bute. Reference was made to the excavations commenced some twelve months back in the gardens of the castle east of the North Road, and soon our correspondent found he had come across Mr. Fowler at an exceptionally opportune moment. In fact, that gentleman was rejoicing in spirit over the discovery—the rich reward of his patient investigations—of the site of the house of the Grey Friars.

Five centuries ago two small houses were founded at Cardiff—one, the Black Friars, by Richard de Clare, "without the west gate"; the other, the Grey Friars, "without the north gate," by Gilbert de Clare, son of the nobleman already mentioned. There is also reason to believe that a Priory of Benedictines existed in the town. The site of the Black Friars (within the castle grounds on the borders of the Taff) has been cleared by the Marquis and preserved for future generations; but the exact position of the Grey Friars was, till a day or two ago, a mystery; hence the quiet enthusiasm of Mr. Fowler, whom we very heartily congratulate. On Speed's quaint plan of Cardiff, drawn up three centuries ago, the Black Friars is distinctly marked, but there is no trace of the companion house, though a residence of considerable pretensions appears, perhaps the mansion of the Herberts. Prior to the building of the latter the dissolution of the monasteries had taken place, and the only use to which the Grey Friars remained to be put was the contribution of its hallowed stones to build the mansion of the Herberts and the tiny houses which did duty for the Cardiff of that day.

The excavations of Mr. Fowler, at the instance of Lord Bute, were commenced some twelve months ago in the immediate vicinity of the Herbert ruins. But though the domestic part of the Grey Friars was then laid bare, not a trace of the church appeared, and the excavators were about giving up in despair when their perseverance was rewarded by the unearthing of several arcade piers and other fragments, which left no doubt whatever of the scene of operations being the site of a thirteenth or fourteenth century church, of greater magnitude than the present fabric of St. John's. We must congratulate Mr. Fowler (who is following up the discovery we have outlined) on the happy outcome of his exertions, and townsmen, too, will feel that they owe a debt of gratitude to the Marquis, whose enlightened munificence has made possible one of the most interesting and important discoveries of late years in the neighbourhood of Cardiff.

THE END OF THE ARCHITECTURAL PUBLICATION SOCIETY.

A GENERAL meeting of subscribers to the Architectural Publication Society was held on the 11th inst., Mr. T. Hayter Lewis (honorary treasurer) in the chair.

The secretary read the advertisement convening the meeting, and the minutes of the last meeting, on April 30, 1888, were read and confirmed. The report, of which we have already given an abstract, was presented to the meeting.

On the motion of the Chairman, seconded by Mr. J. T. Christopher, the report was received and adopted.

Mr. Cates stated that he had had several applications from gentlemen to buy up remainders, but in view of the distinct pledge given by the committee not to at any time allow the issue of copies at less than the original subscription price, in order to guarantee the subscribers against any depreciation in value by a remainder being thrown upon the market, he had been unable to accede to any of the applications.

After some discussion as to different libraries to which it would be desirable to present copies of the Dictionary, it was moved from the chair, seconded by Mr. Hansard, and carried unanimously: "That the honorary secretary be requested to take charge of remaining stock to supply such demands for complete copies as may be made within twelve months from this day; and if any should then remain unappropriated to present them as follows:—(1) To the Royal Institute of British Architects; (2) to the Imperial Institute Library; (3) to the British Museum; (4) to the Royal Institution; and others at the discretion of the honorary treasurer and honorary secretary and Mr. Papworth."

The next resolution, moved from the chair, and seconded by Mr. Wyatt Papworth, was as follows:—"That, after the lapse of twelve months, the honorary secretary be authorised to exercise his discretion as to parting with or destroying the remaining stock of odd parts, and that the numerous wood blocks be offered to the Royal Institute of British Architects, and, if not accepted by them, be also destroyed."

The Chairman then announced that when the stock was finally disposed of it was anticipated that there would be a balance of about 160*l.* unappropriated. He reminded the meeting that at the date of their last meeting, in April 1888, the audited statement of accounts showed that the balance available at that time to meet the current expenses was 99*l.* 8*s.* 3*d.*, a result which had only been attained by an act of self-sacrifice on the part of Mr. Wyatt Papworth. When the production of the Dictionary was resumed, it was arranged that the remuneration to be paid to Mr. Papworth for his labour should be at the rate of 1*l.* 11*s.* 6*d.* for each printed page of the Dictionary; but after some progress had been made with the letter P, it was found that if the funds in hand were to be made sufficient to carry on the work to the end of the letter S, that already inadequate remuneration should be reduced

to the still smaller sum of one guinea per printed page. Mr. Papworth, in his earnest desire to see this great work, which originated with him; and which has occupied so much of his active life, brought to a satisfactory conclusion, generously offered to devote himself and his collections to the bringing out of the remaining letters, and to accept the like utterly inadequate payment for his services. He desired, therefore, to move from the chair, "That, as it appears from the report that there will remain an unappropriated balance of about 160%, it is hereby agreed that 100% of that balance be presented to Wyatt Papworth, Esq., as a small recognition of the self-sacrifice which he has made in carrying out the work of the Dictionary as specially noted by the committee in their report of April 27, 1888." He further stated that the only other suggestion for the appropriation of the balance that had been received by the committee was to the effect that it should be expended in reprinting the "detached essays" with their plates and the plates published 1848-52 in anticipation of the Dictionary; but inasmuch as the balance of 160% would not in any way suffice for that purpose, he thought it better not to formally put the proposition before them.

Mr. Rowe seconded the resolution, which was carried unanimously.

The Chairman then stated that while Mr. Papworth's active co-operation had been indispensable, it was also beyond question that the work never could have been carried through with Mr. Papworth or without him, had it not been for the energetic co-operation of the honorary secretary, Mr. Arthur Cates. From first to last he had made up his mind that the work should be a success, and when in 1888 there was a question as to whether subscriptions would come in and the funds would be sufficient, Mr. Cates had offered to guarantee its completion. In Mr. Cates's presence he did not like to say all he felt, but he warmly commended to the meeting the following resolution, of which he was sure they would heartily approve:—"That so much of the balance of about 63% as can be safely employed, after allowance for possible expenses, be made over to a committee, with power to appropriate the said balance in such mode as they may find most agreeable to Mr. Cates in recognition of the very great services which he has rendered in securing the completion of the Dictionary."

The resolution was carried with acclamation.

The following gentlemen were elected to form the committee:—Mr. Macvicar Anderson, President of the Royal Institute of British Architects, Professor Aitchison and Professor Hayter Lewis.

Mr. Papworth and Mr. Cates both thanked the meeting for their kindly expressions towards themselves and for the resolutions which they had passed.

It was then proposed and carried that should the balance be larger than was expected the difference should be added to the 100%, which was to be handed to Mr. Papworth.

After a cordial vote of thanks to the chairman for his services as honorary treasurer for so many years and for presiding on the present occasion, and also to Mr. Cates, the honorary secretary, and Mr. Wyatt Papworth as the working members of the society for the energy with which they had carried the work to its completion, on the motion of the chairman, seconded by Mr. Rickman, it was resolved, "That the funds and property of the Society be handed over to the honorary treasurer, honorary secretary, and Mr. Papworth to be appropriated in accordance with the preceding resolutions, and that the Society be dissolved from this day."

HIGH BUILDING IN BALTIMORE.

ACCORDING to a correspondent of the *American Architect*, the spirit of high building has reached Baltimore, but with such lagging footstep did it approach, and so long after it had already become a familiar and essential feature in even much smaller cities, that, did we not unfortunately feel more certain that a lack of confidence and enterprise had much more to do with the matter, we might almost have felt that a sense of discretion and fitness hesitated to thrust the new and doubtful innovation upon us, with our unrestrained capacity for lateral extension, and our old existing types of low and broad architecture. However, it is present with us now in a mild form comparatively to the prevalence of the epidemic in other places but with most of its important features, and while the lateness of its arrival may bring the mitigating circumstance that fewer of the abnormally high buildings will be erected before a reaction of opinion and restricting ordinances begin to control excessive height, it may also have the unfortunate result that those which shall have already sprung into existence will stand isolated, conspicuous and hideous, destroying all symmetry and uniformity, and lacking even the somewhat impressive effect of continuous and uniform bigness that may be attained in the streets of some other cities. The marked architectural feature of last year in Baltimore was undoubtedly the advent of this style, as shown by several large

office and bank buildings and one or two apartment-houses, and the one building that is unquestionably more worthy of note than the others is the Equitable, on the site of the old Barnum's Hotel. This building, as a type, would easily be ranked among the other best ones of the same class, of about similar dimensions and cost, erected in the last few years in many of our larger cities, the conditions to be met resulting in a good deal of similarity of arrangement and of exterior design, with like merits and defects, to a large extent, appearing in all of them. The form of construction is, of course, the usual iron and steel skeleton method that now universally obtains. Two points are worthy of note in regard to the contractor's work: one being that among the eight or ten contractors who were the original bidders the average of those from out of town was about one hundred thousand dollars less than that of the Baltimore men, on a total cost of less than one million; another point attracting public attention was the diligence and systematic method with which the work was done, and the absence of obstruction outside the lines of the building itself, in favourable contrast with the inconvenient occupation of a large portion of the adjacent street in most cases where work of any extent is in progress. The building is a ten-storey structure of granite, buff brick and terra-cotta, an agreeable mass of colour, with as satisfactory disposition of solids and openings as the requirements of a huge office building usually admit of, and with rich Renaissance details, appropriately treated in the different materials of both exterior and interior. As to the strictly architectural impression produced—the result seems very much the same as that of other similar buildings, even the most successful, throughout the country. The lightness of walls that are only screen-work, filling in the construction, and not the real building itself, produces shallow reveals and lack of shadow about all openings that give a general appearance of thinness and weakness, the more evident the larger the building. The difficulty of designing a cornice as a grand crowning feature in proper proportion to the immense wall-height below it, and to admit of the practical requirements of the upper storey, is also felt, as well as the question of varying the exterior treatment of so many similar storeys with any intelligent reason that may not seem a mere fancy, and with a design that will take its proper place in the whole scheme. The substitution of numerous elevators for a grand staircase in buildings of this class is certainly the loss of a great architectural feature, which ages of tradition and a certain sense of fitness and completeness still call for in the name of architecture and art, and refuse to be satisfied by the replies of mechanical theory and practice, and, indeed, the extremely subordinate place to which the staircase in many of these buildings is relegated appears to us, from the most practical point of view, almost a criminal error, in the event of possible emergencies when the elevators would be almost useless.

Let us award to this style of building—"style," if we must, *faute de mieux*—all possible merit that the best of them can claim as actually good, because actually representing the spirit of the age. Is this a real architectural merit that we are recognising after all, or is it not rather that the spirit of the age does not ask for architecture but only engineering, with the largest financial returns for the amount expended and space occupied, and only such architectural features superficially applied as will satisfy the vulgar taste for ornament and ostentation, equally satisfactory to the majority of the public when used by an ignorant charlatan or when designed by a cultivated and intelligent artist? If truth is the standard to judge by, then the best of these tall buildings are those where these falsely applied architectural proportions to the wall surface are frankly abandoned, as being "an outward and visible sign of an inward and spiritual grace" of a real construction, and where the wall surfaces that fill in the spaces of the concealed metal structure are simply pierced with openings that sufficiently give access and light to the interior, and tell the true story of the building's purpose. We do not say that appropriate ornament may not be found to give beauty to these wall surfaces and openings, or that the principal perpendicular and horizontal lines of the structure beneath might not be, to a certain extent, indicated on the exterior in the true spirit of design. Nor do we say that this method of construction is not, from many points of view, a very excellent practical way of housing the people of the nineteenth century, with a certain impressive effect about it from mere bigness, but we must admit that if all we have learned to call architecture, from prehistoric times till to-day, and which attained its epitome of perfect beauty of fitness and proportion in Greece, is one thing, then the modern ten or twenty storey building is another; if Athens and Rome and the Middle Ages and the Renaissance and Paris is one thing, in their monumental dignity, symmetry and repose, then New York and Chicago and the spirit of the age is something else which is not dignity, symmetry nor repose; nor, in spite of apparently vast new sources of knowledge, can the average humanity of to-day claim any great physical, intellectual or moral superiority, or greater capacity for real happiness, or any nearer approach to heaven

on the top of the Eiffel Tower than in the shadow of the Parthenon.

Baltimore will probably never have a rival to either of these typical expressions of their times, but she is said to have expended fifteen million dollars in her building operations for the year 1892—in no one edifice specially worthy of note, beyond the one already mentioned, but, to help house her thirty-six thousand new inhabitants gained in the same year, she has built her usual number of small and characterless dwellings, with here and there an individual house cropping up, marked by the effort to assert itself in somewhat larger dimensions and more expensive materials—and a very large amount of carved ornamentation. The majority of these designs seem to come from the same source, and, while not degenerating to the point of an “aberration,” are without artistic reserve or architectural interest; the florid ornamentation is applied as an after-thought and not as an essential part of a scheme, and with a painful disregard of the proper scale or application of details. These houses, however, seem to meet with popular approval.

NEW BUILDINGS.

Birmingham.—Alterations and additions have been completed to Messrs. Pickard & Lloyd's “Tool Works,” situated in Woodcock Street, Birmingham. This building, which was erected probably during the latter part of the last century, has practically been remodelled. The old blacksmiths' hearths and fittings, workshops, &c., have been removed, and others of a more modern and improved kind substituted. A large blacksmith's shop covered with glass, and with louvre ventilators and a spacious two-storey tool-shop, &c., have been erected, so that a previous inconvenient and dilapidated building has been transformed into a well-arranged and substantial one. The work has been carried out in a satisfactory manner by Mr. Shergold, builder, of Aston, from plans prepared by and under the superintendence of the architect, Mr. J. Statham Davis, of Birmingham.

Horsham.—A new Grammar School was opened at Horsham on the 29th ult., providing accommodation for a hundred day scholars and twenty boarders. These new buildings owe their existence largely to the Mercers' Company, a distinguished member of which—Richard Collier—founded the school in 1530. The buildings form a large block on the Hurst Road, near Horsham Station, and the site occupies three acres of land nicely laid out for gardens, playground, cricket-field, &c. The materials are of red brick, Horsham stone, and Staffordshire tiles, built in sixteenth-century Gothic style. The contract for the whole of the work was entered into with Messrs. Potter & Son, Horsham, builders, at 5,795*l.*, and the work has been finished within the allotted period, the total cost being, as adjusted, 3*l.* 6*s.* 8*d.* less than the contract sum. Mr. Arthur Vernon, of 29 Cockspur Street, Charing Cross, was the architect.

Four-inch v. Six-inch Drains.

Appeal to the London County Council.

Sir,—I have been much interested in a recent appeal to the London County Council *re* four-inch v. six-inch drains, and as the subject is of great importance to the public generally, I ask the favour of your inserting the enclosed correspondence in your next issue.—I am, dear Sir, yours faithfully,

SHARTMAN WANSBROUGH.

Arlington Villa, Barrow-in-Furness :
May 15, 1893.

Dear Sir,—Permit me to express my warmest appreciation and thanks for the determined manner in which you have recently upheld one of the most important laws relative to house-drainage, in appealing and reversing the requirements of the Fulham Vestry to lay six-inch drains to thirty small houses. The decision of the London County Council in favour of four-inch drains is a great advancement in sanitary construction, and will undoubtedly prove invaluable in the hands of other sanitarians, when appealing against the use of six-inch drains, to be able to cite as a precedent the decision which you have been the means of securing from such a powerful authority as the London County Council.

I may mention I have had many six-inch drains taken out which have been a continual nuisance in becoming fouled, and by substituting four-inch drains to the same fall as the old six-inch drains the nuisance has been completely remedied, without in any way altering the flushing arrangements which existed.—I am, dear Sir, yours faithfully,

SHARTMAN WANSBROUGH.

Ernest Turner, Esq., F.R.I.B.A.

246 Regent Street, London :

May 16, 1893.

Dear Sir,—I thank you for your letter of yesterday's date, and hope the case will be a useful precedent.

I have no objection to your communicating with *The Architect* as you propose; indeed I think a statement of your own experience may help forward a good cause.—I am, dear Sir, yours faithfully,

ERNEST TURNER.

Shartman Wansbrough, Esq.

GENERAL.

The Six Days' Auction of works left by the late M. Meissonier—that is to say, of one division of the property—ended on Saturday last. The sums paid amounted in all to 2,216,101 frs.

The Annual General Meeting of the Surveyors' Institution, to receive the report of the Council and the announcement of the result of the election of officers for the ensuing year, will be held on Monday, May 29, at three o'clock. The prizes awarded to successful candidates, in connection with the recent professional examinations, will be presented by the President.

The Annual General Meeting of the Institution of Civil Engineers will be held on Tuesday, the 30th inst., when the report of the Council will be submitted and the Council for the ensuing year elected.

A Bust of the late M. Duc, the architect, who had charge of the reconstruction of the Palais de Justice, Paris, has been placed in one of the galleries of the building. It is the work of M. Chapu.

The Fourth Annual Congress of the Societies in union with the Society of Antiquaries will be held at Burlington House on Monday, July 10, under the presidency of Sir John Evans.

A Statue of Johann Arany, the Hungarian poet, has been erected in Buda-Pesth in front of the Museum. The sculptor was Alois Strobl.

Mr. Frederic Salmon Growse, the Indian art critic and archæologist, of Her Majesty's Indian Civil Service (retired), died on Friday, of phthisis, at his residence, Thursley Hall, Haslemere, Surrey, at the age of fifty-six.

Prizes amounting to 4,000*l.* have been offered by the French Society of the “Canal des Deux Mers” for projects in connection with the contemplated ship canal between the Mediterranean and the Atlantic.

The Annual Meeting of the Royal Society of Antiquaries of Ireland commenced at Kilkenny on Monday, and during the subsequent days various places of interest in the district were visited.

Dr. Steindorff has been appointed Professor of Egyptology in the University of Berlin. Some years ago he had charge of the Egyptian Section of the Berlin Museum.

The Jubilee Meeting of the Royal Archæological Institute is to be held this year in London, from July 11 to July 19 inclusive.

M. Gabriel Geailles has obtained a part of the Prix Guérin from the French Academy for his book, “Léonard de Vinci, l'artiste, le savant.”

Mr. Horace Townsend will read a paper on “American Silver Work,” at the Society of Arts, on Tuesday, the 30th inst., in the Applied Art Section.

A Party of Members of the Junior Engineering Society inspected the Tower Bridge works, by permission of the engineer, Mr. J. Wolfe Barry, on the evening of Wednesday, the 24th inst. Since the Society's last visit to these works (in July 1892) much progress has been made, the lifting spans having already been experimentally rotated.

An Exhibition of Alsatian Art and Archæology has been opened in the old timber-house, the “Kammerzill,” opposite the cathedral in Strasbourg. Over seven hundred examples are shown.

Mr. Walter Severn, president of the Dudley Art Gallery, who in 1885 presented the Adelaide and Melbourne Art Galleries with some of his characteristic and picturesque water-colour drawings, has just presented the Sydney Art Gallery with another of his pictures.

Beethoven's House, in Bonn, is now restored to a condition corresponding with its appearance in 1770, when the composer was born in one of the garrets. On the 10th inst. the Beethoven Museum in it was opened.

The Society of Architects has been registered with a limited liability by a licence from the Board of Trade to dispense with the word “Limited” as an addition to its name. Objects: To acquire and take over the assets and liabilities of the unincorporated association known as the Society of Architects, established in 1884. The membership is limited to 500, and each is liable for 1*l.* in the event of winding up.

The Architect.

THE WEEK.

It is not often there is so remarkable a contrast of entertainments as was to be witnessed on Saturday in Sheffield Park, near Brighton. The owner is among the most enthusiastic supporters of cricket, and on that day there was a match in the grounds between the Sheffield Park and Barcombe Clubs, when the former for six wickets achieved 371 runs. As the victory was safe, Lord SHEFFIELD and a party of his friends found time to assist at the unrolling of a mummy in the pavilion, by Dr. BUDGE of the British Museum. It was brought from Egypt by his lordship a few months ago. The subject was identified as a priestess of Apu. Her name was TA-SHERET-MEHT. Her father's name, it appears, was NES-HERU, a piece of information rarely given, as Egyptian genealogies followed the female side. Apu, which is now known as Akhmim, was an ecclesiastical town. The style of embalming adopted in this case was economical. Instead of a necklace of stones, there was only a representation of one on a sort of breastplate. Ornaments of all kinds were absent. The priestess was probably about thirty-five at the time of her death. It must be allowed that the operation was disappointing, for there were no revelations. TA-SHERET-MEHT may have been too fond of lecturing or comminating, for the embalmers did not open her mouth; and, therefore, during two thousand years her spirit has been dumb. If she and her friends anticipated that one day she was to be displayed in an English park as a counter diversion to cricket we suppose they would have provided for the occasion by a supply of information about themselves, which would be more acceptable than trinkets. Their want of foresight will not prevent anyone who was present from joining in the prayer which accompanied the remains:—"O God OSIRIS, the President of the Underworld, the Great God, Lord of Abydos; O thou God PTAH-SEKER-OSIRIS, the Great God within the tomb; O thou God ANUBIS, the God of the Divine Land, the President of the Hall of Judgment; and O thou Goddess ISIS, the Mighty Lady, the Divine Mother, dwelling within the town of Apu; grant sepulchral meals of oxen and wild birds, and milk and wine; grant incense, and spices, and linen, and all good, beautiful, pure, sweet, and delightful things to the deceased lady, TA-SHERET-MEHT, the daughter of NES-HERU, son of the lady of the house, TA-SHERET-AMSU. Triumphant in judgment, may she breathe the soft breezes of the north wind for ever and for ever."

THE Médaille d'Honneur for architecture at the Salon has been won by ALPHONSE DEFASSE, who gained the Prix de Rome in 1886. In painting M. FERDINAND ROYBET has obtained it through his stirring picture, *Charles le Téméraire à Nesles*. M. CHARPENTIER is the fortunate sculptor, and M. LAMOTTE has gained the medal for engraving. The following are the awards of the ordinary medals in the section of architecture:—1st class medal, M. CAMUT; 2nd medals, MM. GODEFROY & BAUHAIN, NODET, NORMAND, BOBIN; 3rd medals, MM. RIVES, BERNARD, NAUDIN, PETIT, HÉNEUX, MAJOU, YPERMAN; honourable mentions, MM. ANTOINE & ARFVIDSON, BALLÉ, BINET, BOISSEAU, BOUTRON, CHAUSSEPIED, GRAVIO, DELMAS, DESBOIS, ESCHBAECHER, FORTIER, KOCH, LE GRAND, MALO, MASSA & HENRY, MIGNAN, DE MONCLOS, MONTJAUZE, MOURÉ, PILLETTE. Among the paintings it was found that not one merited a first-class medal. In the section of sculpture the first-class medals were awarded to MM. LARCHE and LABATUT, and to M. TONNELIER for his examples of medals.

THE assessor appointed by the Lunacy Committee of the Staffordshire County Council to consider the designs sent in competition for the new County Asylum, Cheddleton, is Mr. C. H. HOWELL. On Saturday he made his report, and under his advice the premiums were awarded by the committee as follows:—1. "(2)," 2. "Spes (1)," 3. "Efficiency." The successful competitors are—1. Messrs. JOHN GILES & GOUGH, 28 Craven Street, Charing

Cross, London, W.C.; 2. Mr. GEORGE T. HINE, 35 Parliament Street, London, S.W.; 3. Messrs. J. G. IZARD & A. B. COTTAM, 5 Bloomsbury Square, London, W.C. The competitive plans and designs will be on public view at the Shire Hall, Stafford, on Monday next and two following days, between the hours of 11 A.M. and 5 P.M.

ON Tuesday the annual meeting of the Institution of Civil Engineers was held. The tabular statement of the transfers, elections, deaths and resignations during the year showed an effective increase of 207 on the previous total of 5,371—or at the rate of $3\frac{7}{8}$ per cent. per annum—while as regards the students, the decrease was 49. The gross numbers on the books on March 31 in 1892 and in 1893 were 6,239 and 6,397 respectively. The strict income had amounted to 20,854*l.* 8*s.* 6*d.*, an increase of nearly 800*l.* on the former year, to which had to be added 3,980*l.* 0*s.* 6*d.* on account of capital, and 442*l.* 10*s.* 2*d.* for trust funds, bringing up the total receipts to 25,276*l.* 19*s.* 2*d.* The general expenditure had been 16,527*l.* 17*s.* 6*d.* (including 7,750*l.* for publications, and for premiums under trust 522*l.* 2*s.* 10*d.*); while there had been invested 8,254*l.* 12*s.* 2*d.* in British railway debenture stocks of the nominal value of 7,000*l.*; thus the total was 25,304*l.* 12*s.* 6*d.* The summary of investments showed that there stood to the credit of the Institution 111,400*l.*, with trust funds of the par value of 15,606*l.* 0*s.* 10*d.*, together 127,006*l.* 0*s.* 10*d.* The ballot for Council resulted in the election of Mr. ALFRED GILES as president; of Sir ROBERT RAWLINSON, Sir B. BAKER, Sir JAS. N. DOUGLASS and Mr. J. W. BARRY as vice-presidents; and of Dr. W. ANDERSON, Mr. A. R. BINNIE, Sir DOUGLAS FOX, Sir CHAS. A. HARTLEY, Messrs. J. C. HAWKSHAW, C. HAWKSLEY, and ALEXANDER B. W. KENNEDY, Sir BRADFORD LESLIE, Mr. J. MANSERGH, Sir GUILFORD MOLESWORTH, Mr. W. H. PREECE, Sir E. J. REED, and Messrs. W. SHELFORD, F. W. WEBB and W. H. WHITE as other members of council.

ON Wednesday the annual dinner of the Architectural Association took place at the Criterion Restaurant, a number of the old members, along with friends and supporters of the Association, being present. Among those whom the president (Mr. H. O. CRESSWELL) welcomed were Mr. MACVICAR ANDERSON, the president of the Institute of Architects; Mr. GEORGE AITCHISON, A.R.A.; Mr. WALTER CRANE, Mr. E. W. MOUNTFORD, the president-elect; Mr. GOLDSMITH, Mr. E. S. GALE, Mr. PAUL WATERHOUSE, Mr. FLORENCE and many other past-presidents and well-known members. It is hardly necessary to say that Professor KERR, who has always been so interested in the welfare of the Association and of students, was present. After a toast to Her Majesty the QUEEN, the President proposed the toast of the Royal Academy. Though one of the best-abused societies in the country, architects had at any rate to thank it for maintaining the classes from which he for one had derived great benefit. Professor AITCHISON, in responding, alluded to one claim the Royal Academy had on their gratitude, inasmuch as its teaching was given gratuitously. In regard to the architectural instruction given, that would depend very much on architects themselves, who should make up their minds as to what they wanted and what was practical. Mr. ANDERSON, in replying to the toast of the Institute of Architects, spoke of the cordial relations existing between the two societies, and of the way in which the examinations had tended to stimulate the cause of architectural education in the country. He also congratulated Mr. CRESSWELL on the good work he had done as President, and anticipated good work in the future from the President-elect. Professor KERR proposed the toast of the evening in his usual eloquent and happy style. He raised a laugh amongst his audience, saying that he considered the architects of England to form the most honest of all the professions, not excepting the medical profession or the Church. He knew of no institution in the country supported by students alone who had done better, sounder or more persevering work than the Architectural Association. Other toasts followed, to the President and officers, the studio, &c. Songs were sung during the evening by Mr. CONSTANDOUROS, Mr. GROSSE, Mr. TATLOCK and others, and a violin solo given by Mr. WILLIS. An old friend of the members, Mr. IMHOF, presided at the piano.

THE GRIEVANCES OF BUILDING WORKMEN.*

IN a time when discontent appears to be one of the agencies for governing the world we cannot expect workmen to be more exempt from its influence than the people above them. If men were always satisfied with their lot there would be few improvements introduced, and it would not take long to bring us all back to a more barbarous condition than now prevails. The cause of discontent nowadays is the scarcity of money. We are all too poor. It may be true, as the Greek CLEANTHES said, that the best way to become rich is to be poor in desires; but it is not everybody, and in the nineteenth century especially, who, like that philosopher, can have the patience to lie abed, deeply thinking, because he has lent his one garment to a brother stoic, and is happy when he gets the chance to earn a few pence daily by carrying water. While we may grant that no wealth is equal to virtue, we must not forget that, as long as we are not entirely spirits, virtue has a very close affinity for substantial things which have to be paid for. Lord BACON once drew a sketch of "a believing Christian," no doubt with the intention of suggesting that his lordship was writing of himself from self knowledge, and the model man, it appears, "is rich in poverty and poor in the midst of riches; he believes himself to be a king, how mean soever he be, and how great soever he be, yet he thinks himself not too good to be the servant to the poorest saint." The difference between the philosophic rascal's profession and practice is not more wide than exists between the words and actions of some modern and well-to-do teachers, who believe that resignation should be acquired at all cost by the humbler classes, and that "the sovereign'st thing on earth for an inward bruise" is some sort of paradoxical parmaceti such as BACON suggests, and which divines, lawyers and philosophers at all times are adepts at preparing. The world is now as out of joint as ever, and it is absurd to suppose that workmen, who have so much to do with the movements, should not be allowed to suggest that a new arrangement of the parts, or the application of some new lubricant would not be an improvement.

The British workman, including the most skilful, have one grievance which would try the virtues of any philosopher, that is, there is a sort of prohibition against following the natural law of development. The trade societies prefer to foster at the most only an average amount of power, and prefer that members should remain below it rather than rise above it. It is not inscribed over the places of meeting that those who enter must abandon all hope of advancement; but practically that is known to be the spirit of the unions. We have only to ask, what has been done during the present century by the leaders of those powerful bodies to promote education or to raise the character of the work produced in their respective trades? We may grant that it is quite possible for workmen as a body, the most politic course to adopt is one which brings all things to a common, if a dead, level of mediocrity. At the same time, it cannot be denied that such a course is most oppressive for many individuals who are prompted by a sort of instinct to attain knowledge and practical power. It impedes their mental growth, and they must suffer in consequence. Is not this a grievance which is more prevalent among British workmen than others elsewhere? At one of the sittings of the Labour Commission Mr. F. A. MOORE, a builder's foreman, who is a carpenter and joiner, but is not a society man, said:—"I hold it ought to be the legitimate and the proper ambition of every workman to have, in the first place, the technical mastery of his own trade, and in time of all the allied trades. Take the case of a workman who simply stops when he becomes a journeyman, and is content with earning his journeyman's wages; there is something terribly depressing about that spectacle, I think." That is, however, a spectacle which is to be witnessed in almost every town in Great Britain and it is not one which is creditable to trades-unionism as a principle. Again, the same witness said he had generally noticed in his own trade that men of the very best ability, both educationally and technically, are practically the most

in the background. He was pressed by Mr. MUNDELLA (who appears to have faith in tracts as a remedial agent for social difficulties, and believes the workman is now more respected and honoured for his virtues than heretofore), about the influence of literature on the working carpenters and joiners. Rather inconsequentially the witness mentioned that he was acquainted with one of the trade who had turned musician and appears on concert stages, and with a joiner's son who is a tenor and can obtain 30s. to 40s. a week. "These are isolated cases," he added, "but you can find them extended largely." The conclusion we suppose that Mr. MOORE had drawn in his own mind was that a man who is eager to succeed must come out of the ranks of carpenters and joiners, and as the affairs of the trades are managed, he would not be far wrong. In America they could practise as architects as well as musicians. The sagacious Mr. MUNDELLA imagined he had caught the witness tripping, and the following dialogue between the two, which we give parenthetically, has interest as revealing the knowledge which our rulers possess about architectural practice:—

But do you think as a rule that men who have not been educated to the profession make good architects?—No. I know as a matter of fact of more than one eminent architect who has been a workman before he became a professional architect.

But does he not undergo examination?—Unquestionably.

And become a member of the Association of British Architects?—Yes.

Then he gets a sort of diploma which enables him to practise?—Yes.

There is nothing to prevent any man doing that? But you are aware that many practising architects in England are not members of the Association; any member will corroborate that.

The building trades call for many varieties of skill, and it seems hard that a man who may possess constructive or artistic powers of a high order should receive the same pay as another workman who is incompetent to exercise much thought, and therefore is inferior to a machine. In Somersetshire, for example, the plasterers are paid no more than 4½d. or 5d. an hour. The wage is too low, but for a man who does ornamental work it appears to be unjust. As the workmen are, however, satisfied to be treated as if possessed of equal merits and demerits, they cannot be surprised that masters are chary about attempting to distinguish those who deserve notice and reward for industry and ability. Professor MARSHALL, who represents political economy on the Commission, stated that a great number of employers informed him that they would gladly pay higher wages to deserving men, and that their only reason for not adopting that course is that they have found the giving extra pay to some men causes a strike on the part of the inferior men. Apart from ability there is the important difference in the possession of tools, which in some trades means a corresponding difference in productive power. Mr. MOORE expressed the feeling of the men whose pride in their work has not been overcome by the unions when he said:—"I do not like to find myself on a Saturday going to the pay-office and getting just the same as the most inefficient man in the shop. Perhaps I have a hundred pounds' worth of tools to begin with; I dare say in my time I have spent quite that in tools alone, and I find myself on the Saturday receiving the same wages as a man whose tools could be bought for 15s., all the tools he has on earth. It is things like that that operate to discourage men." All such evidence (and much more could be cited) should be sufficient to convince an intelligent workman belonging to a building trade of the way his condition is affected by his fellow-workmen, and he must see that as long as the standard to which he must subject himself is that of an inferior workman, he cannot expect fair play from builders or their employers—the public.

The workman in the building trades makes light of what he endures on account of his fellow-workmen when he considers all that contractors can inflict on him. His grievances under this head may sometimes be imaginative, but often they are too real. Some of them are modern. Every architect knows, to his cost, that the business of contracting has gone through many modifications during recent years. It can no longer be certain in every case when dealing with a contractor that one is sure to meet with a man who has had some training for his position in a workshop or on building works. That undefinable being,

* *Minutes of Evidence of the Royal Commission on Labour, Her Majesty's Stationery Office.*

"a business man," who is ready to undertake all sorts of risks so long as there is a chance of profit to be derived from them, has invaded too many trades. Without experience or training he is ready "to run" theatres or dispensaries, assurance companies or bakeries, chapels or creameries, separately or conjoined, with equal avidity. Sometimes he holds an interest in an architect's office, but of the two he prefers a builder's business. He knows there is a glut of specialists of all kinds in the markets, and he invests in them as he would in a piece of machinery or a sky sign. We are afraid he is responsible for the majority of the complaints which were brought before the Commission by workmen of the building trades. If a similar inquiry were instituted twenty years ago there would be carpenters, masons, bricklayers, plumbers and painters who could testify to the existence of arrangements that did not meet with their approval, but the case against contractors would be, unless we are mistaken, conducted on different lines.

It is through the influence of the new spirit which comes from the connection of speculators with building that so many efforts are made to deceive architects by substituting inferior work or materials, in order that the amount of profit from contracts can be increased. What does the genuine City man care about keeping up the traditions of good building? His interest in that sort of business may only be temporary, and his ambition is to render it as productive as other ventures. Knowing so little about the execution of works, he adopts the course which is common with commercial ventures, and endeavours to get rid of risks by means of sub-contractors. Unfortunately he finds imitators among men who were trained as builders, and should be proud of their business.

It was characteristic of Mr. MUNDELLA that he could not understand why workmen should make any grievance out of the irregular conduct on the part of their masters. Hands are not to assume the censor's office. As long as they are paid their wages they should be satisfied. A plasterer in his evidence spoke about a strike of his trade at one public building where they believed some of the piecework "was being scamped to the highest degree." Mr. MUNDELLA asked him, "If you were receiving the regulation wages and working the regulation hours what ground had you for that strike?" When the witness replied, "Because the work was not being done as they considered it should be done in accordance with the specification," he was pulled up sharply with the question, "That was not your business, was it?" and the witness was made to feel that what plasterers sought after was not better work but a slower execution of work for their own convenience.

The late Mr. BRIGHT convinced himself that adulterating was a legitimate element in business, and we suppose defective work, if it can escape the architects, should also be tolerated as part and parcel of the most modern system of production. But if workmen more often refused to make use of unsatisfactory materials, or to carry out orders for scamping, would it not be an advantage to the community? Mr. DEW, the secretary of the London Building Trades Committee, in his evidence referred to those London Board Schools which are falling to pieces as examples of a pernicious, if approved, system of contracting. He said:—"This had become so bad, this had become so unbearable, and the workers had suffered, having been forced and hurried in their work, working under cruel taskmasters, doing their work in an inferior and scamping manner, that they determined to put a stop to it." As long as evils are overcome, the nature of the agency employed is of secondary importance, and the public have reason to be grateful to any class of men who will aid in preventing a repetition of abuses like those of the London School Board, and for which facilities are given by the system of local government. As defilement follows the touching of pitch, so it is impossible for any man to assist in carrying out contracts in a dishonest way without becoming demoralised. The men also know that a contractor who will sacrifice every interest to profit will not draw the line at materials or workmanship. They must expect that he will, when dealing with them, interpret his obligations in his own way, and for that reason they have a right to be on their guard and to watch his tactics.

The evidence given before the Labour Commission by

workmen is mainly directed against the agency of sub-contractors. Mr. MUNDELLA, who made himself prominent in the inquiries, appears to confound sub-contractors with contractors for specialties. When a carpenter was telling him about men being employed at joinery in gangs on the piecework system the Chairman remarked:—"Surely there are some great plumbing houses of London who do all the sanitary-fitting, closets and so on, and all the plumbing from top to bottom, and who have not only a London reputation but a reputation all over Europe—the best hotels in Europe are fitted up by these men," and his words would show that Mr. MUNDELLA believed that all sub-contractors were as renowned as Messrs. JENNINGS or Messrs. DOULTON are in sanitation. When their names appear in architects' specifications they no doubt belong to a select class. But the mens' notion of a sub-contractor is a taskmaster, who has to get work done so quickly as to insure profit for himself and others above him; he is a magnate who is not easily impeded, and is not over-particular about the means he adopts to achieve his ends. In one case we hear of a sub-contractor who adulterated the specified KEENE'S cement with from 30 to 50 per cent. of lime and plaster. With contractors for brickwork a favourite dodge of getting work done expeditiously is the following:—

A taskmaster will take the job of laying bricks on a building at so much a thousand or so much a yard, or whatever the system agreed upon is. Then the taskmaster will employ, perhaps, a couple of men who are well known in the trade by the name of "bell horses." I will just explain what this means. Probably they are two of the strongest and most lusty men he can get; he will give them, perhaps, 3d. or 4d. an hour more than he will give to the other men. They have got to push the line up; that is, to take the corners and some of the leading parts of the building and push the line up as quick as they can, and the general gang of men who are working along it have to keep up level as the line is moved, or otherwise they have to be discharged.

It will be said that a contractor is obliged to adopt strategy of that kind to compel men to put energy into their work, for with members of trades unions the rate of progress is set by the weakest or less efficient member of a gang. But other cases were mentioned which suggest that what is sought is expedition, even at the expense of substantial work. Take the following as an example of what is done in woodwork:—

Speaking of my own particular trade—I am myself a carpenter and joiner—the sub-letting leads to many evils. It leads to scamped and inferior work. Perhaps you will understand readily if I illustrate my meaning by a door. Of course a door requires very careful preparation. Its joints require to be well fitted, and then in putting it together it should be thoroughly cramped and glued, but when you are doing it on the piecework principle you have taken the door at a certain price, and, of course, you want to make it pay. The glue-pot is not hot, the glue is not ready, and in many cases the door goes together without glue at all. Then sometimes you wonder why your doors are cracking and falling to pieces in your houses. You may get a fair price for some doors or sashes or frames, or whatever it might be to-day, and you would earn, perhaps, at the end of the week a reasonable amount of wages; but there will be another lot of doors to be made the week following, and the employer will say, "Oh, you have made so and so out of this; I shall only give you so and so for the next lot," and then, perhaps, you cannot find employment elsewhere, and you are practically compelled to take what the employer offers.

We find a representative of the house-painters also testifying to the want of thoroughness in the completion of work:—

I have great objections to raise against the system under which the work is done, and I would like to find or to suggest a remedy with reference to that. I allude more especially to the cases where work is scamped in an outrageous manner, and unskilled and inferior workmen are employed in a most unfair manner, causing serious injury to the workmen and to the public also. By employing unskilled labour in the place of skilled, and by scamping the work, this evil arises. The remedy is obvious: the employment of skilled labour and skilled supervision. I think there is an important point that may be dealt with in reference to the skilled supervision of work. As it is, the work is allowed to pass muster no matter how inferior it is got up, provided it looks well from the surface, or provided it passes.

London seems to be the region where the sub-contracting system appears in its least agreeable aspects. In the country there are not always buildings on a scale of sufficient magnitude to tempt speculators to meddle with them, and people are not so ready to pay big prices for extraordinary expedition in completing works. The provincial witnesses appeared to know of the system only by hearsay. According to a witness from Liverpool (it is true he represented the builders) the system of sub-

contracting works satisfactorily in the North. In Scotland separate contracts are common; but, unless in railway works, there are no sub-contractors who supply labour only. A Glasgow mason stated that, as far as his experience went, piecework or tasking was generally of an inferior class.

All lovers of good building will be likely to side with the workmen, for, as one of the witnesses well said, "that building over the way, the great Abbey, that was not carried out by a pushing and driving energetic foreman"; it was carried out by the "master workmen." But the men who were employed at Westminster Abbey could hardly have adopted principles like those of the unions; as far as we know, there was no impediment to a mason putting forth all his strength. The modern system of sub-contracting is mainly to be ascribed to commercialism, but there is no doubt the men themselves have helped to make it necessary. When a builder finds that with old-fashioned ways of dealing with his men his contracts do not pay, it is only human that he should be tempted to follow the course which novices in contracting find to be profitable, that is, to obtain the services of foremen or sub-contractors who are despots, and will control the workmen as rigorously as the law will allow. The prices at which work has to be undertaken can often become remunerative only on the supposition that workmen will become more active in order to secure employment. Men will not pay much attention to that theory, and, moreover, they believe the majority of contracts are profitable to somebody. In such cases contractors cannot be expected to accept ruin through a fear of wounding the susceptibilities of workmen by keeping an eye on the quantity of carpentry or masonry that is produced, especially as they must know that any sacrifice on their part will not excite gratitude.

(To be continued.)

GLASGOW INSTITUTE OF ARCHITECTS.

A MEETING of the Glasgow Institute of Architects was held on Thursday, the 25th ult., the president, Mr. W. Forrest Salmon, in the chair. The following correspondence relating to the recent by-laws framed under the Building Regulations Act was read:—

115 St. Vincent Street, Glasgow:
April 8, 1893.

Mr. J. Lang, City Chambers.

Sir,—In response to the Lord Provost's request to know as early as possible the result of my council's meeting, which was held after the meeting with your committee, regarding the building by-laws, I wrote to his lordship on the 27th ult., informing him that my council had agreed to recommend the Institute to withdraw its opposition to the proposed by-laws.

I have now to inform you that the recommendation of the council has been confirmed by the Institute, and I enclose an excerpt from the minute of the general meeting, which records in detail the reasons which have led the Institute to agree to withdraw its opposition.

I shall be glad to hear from you before sending formal intimation of withdrawal to the Secretary for Scotland.—Yours truly,

C. J. MACLEAN.

Excerpt from minute of the quarterly general meeting of the Glasgow Institute of Architects, held at Glasgow on Thursday, March 30, 1893. President W. Forrest Salmon in the chair.

The Sub-Committee on Building By-laws having reported to the council the result of a second interview which they had with the Committee of the Police Board, the council agreed to recommend the Institute to withdraw its opposition to the by-laws on the understanding that by-law No. 73 would be struck out, and that it was the intention of the Town Council to prepare in a year or two a Building Act for Glasgow more thorough in character than the existing Acts, and to consult with the Institute when framing the clauses. On the motion of the President the Institute adopted the recommendation.

NOTE.—At both of the interviews great stress was laid by the Commissioners upon the temporary character of the present Building Act and by-laws and the certainty of further and more complete legislation in "a year or two." Attention was directed to section 12 of the Act, which gives the Dean of Guild Court discretionary power with regard to the provisions of the Act and by-laws, and it was asserted that under this section any enactment that was found to be unnecessary or oppressive would be relaxed, while every opportunity would be given to architects to introduce materials and modes of construction other than those prescribed. It was pointed out that section 72 of the Act empowers the Secretary for Scotland to allow or disallow any by-law, but not to amend or alter it, so that the consequence of pressing the Institute's objections would be that, where

these were given effect to, the by-laws would not be amended as the Institute desired, but would be lost altogether. The Commissioners admitted that a considerable proportion of the objections were well founded, and acknowledged that the action of the Institute had been directed to the promotion of good building.

By-law No. 3, Drawings.—This was a question merely of the scale of block plans, and the matter will be dealt with in any future enactment.

By-laws Nos. 9 and 10, Mortars.—The only difference of opinion here was with reference to Portland cement mortar, and as the Institute approves the by-laws so far as other mortars are concerned, it was not thought necessary to press the point in the meantime.

By-law No. 11, Concrete.—The sub-committee adheres to its opinion that this by-law provides for an unnecessarily large proportion of cement in Portland cement concrete. The necessity for some restriction was admitted, and as the only alternative to leaving the by-law as it stands seemed to be its total deletion, it was thought better to leave it. It was also stated that the by-law referred to concrete in foundations, and that it was not applicable to concrete used otherwise, and further that the matter would be fully considered in any future enactment.

By-law No. 15, Thickness of Walls.—The principle which the Institute contended for, that walls ought to be classified in determining their thickness, was fully admitted. The by-law was acknowledged to be incomplete and imperfect, and its development in the manner referred to in the objection was promised.

By-law No. 29, Safe-loads for Floors.—It was admitted by the committee of the Commissioners that the safe-loads prescribed would be in many cases excessive, but it was pointed out that there was no power to prevent a building which was erected for one purpose being afterwards used without alteration for a different purpose, and one, it might be, involving much heavier loading of the floors. If such power was obtained this by-law might be greatly relaxed. It was also stated that temporary buildings of every kind were exempted from compliance with the by-law.

By-law No. 35, Roof-lighted Stairs.—It was admitted that this by-law was defective. In view of the importance of having common stairs adequately lighted and of the dispensing power of the Dean of Guild Court, it was strongly urged that it should be allowed to pass as a temporary provision, which would be enforced only so far as it was considered desirable by the Dean of Guild Court.

By-law No. 73, Stairs in Public Buildings.—It was agreed to delete this by-law.

City Chambers, Glasgow: April 10, 1893.

Dear Sir,—I am in receipt of yours of 8th inst. informing me that the recommendation of your Council has been confirmed by the Institute, and enclosing me excerpt from the minute of the general meeting which records in detail the reasons which have led the Institute to agree to withdraw its opposition.—Yours truly,

C. J. MacLean, Esq.

J. LANG.

City Chambers, Glasgow: April 10, 1893.

Dear Sir,—In reply to yours of the 8th inst. (already acknowledged), I am directed by Bailie Primrose, the chairman of my committee, to thank your Institute for the withdrawal by it of its opposition to several of these by-laws, and to express the hope that your Institute will at the earliest possible convenience inform the Secretary for Scotland of that withdrawal, so as to admit of the by-laws being forthwith confirmed and put into operation.—Yours faithfully,

C. J. MacLean, Esq.

JOHN LINDSAY.

115 St. Vincent Street, Glasgow: April 12, 1893.
The Under-Secretary for Scotland,
Dover House, London.

Sir,—I beg to enclose excerpt from the quarterly general meeting of this Institute, held on the 30th ultimo, agreeing to withdraw their opposition to the by-laws under the Glasgow Building Regulations Act, for the reasons stated in the excerpt, and I further formally intimate that the opposition is now withdrawn, except as to by-law 73.—I am, &c.,

C. J. MACLEAN.

Office of the Secretary for Scotland,

Whitehall, S.W.: April 13, 1893.

Sir,—I have to acknowledge the receipt of your letter of the 12th instant and enclosure.—I am, &c.,

COLIN SCOTT MONCRIEFF.

The Secretary, Glasgow Institute of Architects,
115 St. Vincent Street, Glasgow.

THE TEMPLES AT GIRGENTI.

A CORRESPONDENT of the *Manchester Guardian*, who is travelling in Sicily, gives the following account of a visit to the ruins at Girgenti:—

The Greek "Akragas," the Roman "Agrigentum," stretched at one time from the hilltop on which the modern town now stands down to where a natural terrace of rock separates the hillside from the lower level near the sea. Along this rampart, which was worked up into a wall, the temples were built, and there they are still to be seen in a mighty row, two still standing upright, the rest, destroyed by enemies and earthquakes, lying

in ruinous heaps. How the city must have looked when it held 40,000 inhabitants and occupied the whole hillside, its lower boundary rimmed by temples which glistened with a marble-like coating, and were decorated with sculptured ornaments picked out in many colours, we can hardly conceive; but even now the sight is lovely. The buildings, with the coating worn off, show the original colour of the stone, a warm golden tint, and they stand out grandly on the edge of the old wall, since honeycombed with early Christian graves and catacombs. Between the huge fluted columns, through which the wind whistles eerily, we look down upon the low land and the sea beyond, and upwards to the rising country, green with almond-trees in freshest leaf, and violet in the shadows where the passing clouds sweep over the hillsides. How magnificently the Greeks chose and used their sites is one's first reflection, and the next how beautiful is the setting which nature and a happy climate have given to the ruins of their handiwork. Grand monuments, just saved from gauntness by their soft colour, set among the freshest and most charming landscape—truly a sight not soon to be forgotten. Around the temples grow the small dwarf palms whose form is seen again in the ornaments which crowned the temples, as may be studied with many another detail of their decoration in the museum at Palermo. This is another reason for taking Palermo last. See first, at Segesta and Selinunte as well as Girgenti, the dry bones of the temples; then learn at Palermo how the bare forms were clothed with plastic ornament and brightened with varied colour.

TESSERÆ.

The Province of Art.

TO define what we mean by art in general is a somewhat difficult task. It is difficult to furnish not only a correct, but a complete definition. We may say too much or too little, including more in its domain than legitimately comes within its province, or excluding some of its proper functions by drawing our limits too close. If we may venture upon a definition of art, we should describe it as the contrivance, the method, the system by which the human mind makes use of the material world for its own purposes. It is, indeed, the necessary result of the position of an immaterial being, clothed in a material body, and placed in the midst of a universe from whose resources it must draw abundantly for the satisfaction of its desires and necessities. The soul within us can hold no converse, save with a pure spirit, without employing the powers of the physical creation in which she dwells. Not only is she compelled to have recourse to them for the preservation of her own state of being, and for the supply of those bodily wants to which she is irresistibly compelled to attend, but without these she can in no way communicate with her fellow-men; she cannot express to them either her thoughts or her feelings. Her divine capacities are powerless until they can avail themselves of the countless objects of sense that surround them, in order to utter those sentiments which are in themselves the operations of the pure, spiritual intelligence. And when she turns to the visible creation of which she finds herself an inhabitant she perceives that not only can she make use of its boundless resources for the support of her present life, for the increase of her enjoyments, for the gratification of her appetites and the charming of her senses, but that, by a certain marvellous and mysterious pliability, this whole universe can be made the instrument by which she pours forth those ideas which have their origin in the depths of her own immaterial essence. Creation is to her not only what it is to the beast of the field, but also the element of a language most wonderfully fitted to convey to others every thought that may arise in her inmost recesses. By the constitution of her being she is capable of a multitude of sublime ideas, of great, pure and noble sentiments, and of tender, reverent, loving emotions, to which by the same constitution she is impelled to give utterance at various times and in various circumstances. Apart from every consideration of utility or experience, she is conscious of a certain intimate connection and relationship with a world of spirits, some of them, like herself, wrapt in the garments of a material mortality, others the denizens of an invisible world, of whose characteristics all she knows is that it is inhabited by spiritual beings beyond the reach of her senses. Then, casting her eye upon the physical universe around her, she perceives that, from the varied laws by which it is governed, and from the wonderful attributes and qualities which its different portions possess, she may draw the means for entering into communion with that which is invisible, and that helpless though she be to communicate directly with aught that is spiritual while it is clothed in a material body, in this land of boundless wealth she may discover means for pouring forth all that she desires to utter. Hence also arises the distinction between "the fine arts" and "the mechanical" or "useful arts." The useful arts, as the term is generally employed, are occupied in furnishing man with what is

necessary to his existence in life, or what conduces to his bodily comfort and luxury. The fine arts, on the contrary, are devoted to the suggesting to the mind certain thoughts and emotions which possess a power to charm, or to the expression of those ideas which the mind desires to communicate through the medium of what is audible or visible. Of the five senses of the body, three are busied with the useful arts, namely, the touch, the taste and the smell; the others, that is the hearing and the sight, are the instruments of the fine arts, the channels by which the sensation of beauty is conveyed to the mind, and by which spirit communicates with spirit.

Coloured Sculpture.

A passage occurs in the 35th book of Pliny, c. 11, directly supporting the practice of colouring the accessories of statuary:—"This is that Nicias (the Athenian painter), concerning whom Praxiteles said, when asked which of his works in marble he most approved of, Those which Nicias has applied his hand to: so much Praxiteles attributed to his tinging (*circumlitioni*)." This last word may be rendered adorning with paint, doing over, or, as its sense is more exactly supplied in the German, *umschmieren*. The work of Sir Charles Fellowes on his important discoveries in Asia Minor has thrown light on the earliest history of Grecian art, and established the identity of cities referred to by Herodotus and others with the remains that indefatigable traveller has been the first to make known. An inscription was found by him at the ancient Aphrodisius, in Caria, to this effect, "That Callias, grandson of Zeno, the son of Eudamus, an honourable and good youth, whose conduct was virtuous and worthy of all praise, be honoured with the greatest and fairest honours; and that there be put up his statues and sculptures and images, painted in golden armour, in the temples and public places, whereon there are also to be inscribed his honours fair, and befitting and becoming his family and the conduct of his life; and that these worthy inscriptions be likewise placed on his tomb, in which his brother Zeno also is buried." Here follows the epitaph. According to this inscription, the temples and public places of Aphrodisius were decorated with statues in painted or gilt armour; for ΕΙΚΩΝ ΓΡΑΨΙΤΗ (the phrase employed) is a painted statue or image of the personage to whose honour the tomb was erected. In a note to the same valuable work of Sir Charles Fellowes, the authority of one of the greatest scholars both in the literature and art of Greece that the present century has possessed is adduced to bear the same testimony. "The satisfaction I received," says the author, "on my return to Athens, in renewing my acquaintance with the justly celebrated Professor Müller, has made me more aware of the immense loss Europe has sustained by the death of one of her greatest scholars in all the vigour of life. On seeing the coloured drawings of this tomb (the author speaks of one he had discovered in Myra, a city of Lycia, the walls of which were surrounded with reliefs entirely coloured), he expressed the following opinion as to the mode of colouring adopted by the Greeks in their works of art:—"The ancients painted their bas-reliefs; they only tinged their statues; tinging the drapery, leaving the flesh part uncoloured; the wounds and blood were stained, and the ear-rings and ornaments gilded. Their temples were left white, but parts of the frieze and architectural ornaments were coloured, but very minutely. Their temples of coarse materials were plastered and entirely coloured. The Parthenon frieze was coloured; all the backgrounds of their bas-reliefs were painted." In further corroboration of this were discovered, some years since, in the excavations at the Count Lozzani's villa, near the Porta Pia, Rome, the three large sarcophagi which are now in the Gregorian Museum at the Lateran Palace, and whose reliefs, as well as the walls of the tomb containing them, were entirely coloured on their first exposure—the wreaths of flowers on one with all the hues of nature, the Orestes pursued by the Furies and other groups, all in well-preserved tints. Since their removal to the museum, from whatever cause, these have almost entirely disappeared.

Painters' Dexterity.

Giotto unquestionably possessed a singular degree of mechanical dexterity as a mere artist. This superiority in executive power is, indeed, no unfrequent accompaniment of the highest order of talent and genius in all divisions of art and mental cultivation. Few men think well who cannot speak well. Verse is generally easy to those in whom the poetic fire burns with brightness. To Michel Angelo the manual use of the mallet and chisel seemed to come by nature. Handel, Mozart and Beethoven played as it seemed almost by inspiration. And so also with the great restorer of painting. The pencil was to him an instrument over which he seemed to possess a natural sovereignty, and the well known proverb, "Più tondo che l'O di Giotto," bespeaks a dexterity in its use such as few painters have attained. When invited to Rome by Pope Boniface VIII., says the story, Giotto was asked by the messenger from his holiness to give him a specimen of his famous powers. Upon this the painter traced upon paper in

a moment, with a single turn of the pencil, a circle so perfect in form that the messenger, and afterwards the Pontiff, were at once convinced that the painter's merits were at least equal to his fame. This story of Giotto's wonderful dexterity of hand reminds one of the well-known anecdote of the two great Greek painters, Apelles and Protogenes. Apelles went to Rhodes to see Protogenes and his works, and, as Pliny relates the incident, found Protogenes away from home, and no one in the studio but an old woman, taking charge of a panel upon an easel, ready prepared for the painter's hand. When the old woman inquired of the visitor what name she could give to her master when he returned, Apelles took a pencil wet with colour and drew a line (*linea*) upon the panel, bidding her show it as the visitor's memorial of himself. Protogenes returning, saw the line, and exclaimed, "None but Apelles could have traced that line." He then took a pencil, and, with another colour, drew upon the same (here the mystery of the story begins, as the pronoun used by Pliny does not show whether he meant "upon the same line" or "upon the same panel"), a yet finer line; and going out again, desired his servant to show it to Apelles when he should call again. Apelles again visiting the studio saw himself outdone, and immediately with another colour drew a third (*secuit lineas*), attaining the utmost limit of fineness; and Protogenes coming home, confessed himself vanquished. This panel, with the three lines, was preserved at Rome in the Imperial Palace on the Palatine, till it was destroyed by fire in the reign of Augustus, so that Pliny never saw it himself, but told the story as related by others. The account itself is full of obscurity, and has been a fertile source of conjecture for the curious.

Imitative and Illustrative Painting.

Among the Greeks, a belief grew up that the painter and the sculptor must follow the descriptions of the poets, as these were held to have anticipated the artist's conceptions, and established a previous settlement on his ground. A recollection of some of the themes which the Greek artists treated, satisfies us that Apelles or Zeuxis, and most of the renowned painters of antiquity, derived their subjects from the mythological or other fables of their time. For his "Jupiter" and "Minerva" Phidias drew on the bards who had excited his imagination with such themes. Homer supplied the moral proportions and relations, and for the physical elements out of which he combined and constructed these ideal personifications of omnipotence and wisdom, he went himself to Nature. The "Venus" of Apelles, the "Helen" of Zeuxis, and the "Galatea" of Raphael drew their inspirations from the prevailing traditions and ideas caught from the poets. That these controlled the respective artists, we learn from the difficulties which each encountered in finding in ordinary nature the forms that would suffice to render satisfactorily the accepted notions with which the public mind was familiar. Michel Angelo, in the Sistine, in his Prophets, and his Sibyls, drew for his grand creations on the inspired portions of the Scriptures, or on the fables of Pagan mythology. To what extent in the Middle Ages the imagery of Dante controlled or directed the imitative capacities of the painter, it were superfluous to mention, except for the purpose of observing that religious principle was as much the motive in that time to both painter and poet, and therefore as necessarily suggested a conformity of action, as it was in the old Pagan period. There have not, however, been wanting opinions which such cases do nothing to justify, that Art is elevated by seeing Nature generally, and, as a rule, through the poet's spectacles. "In some instances," observes Lessing, "it is a greater merit in the artist to have imitated Nature through the medium of the poet's imagination than without it. The painter who has delineated a beautiful landscape, after a Thomson, has performed a higher task than he who has copied it directly from Nature. The latter has the original immediately before his eyes; the former must exert the powers of his imagination until he fancies he sees it before him. The one produces a beautiful imitation of distinct and palpable lineaments; the other has to arrange a discretionary effect from faint and fleeting images." This is dangerous doctrine. Art so derived can at best give but a second-hand impression of Nature. The painter has thus delegated his own power of seeing Nature to another, in entire neglect of the peculiar requirements and technical capabilities of his own art. This opinion of Lessing's shows how capricious and unpractical are some of the dogmas which the unprofessional critic does not hesitate to promulgate, and which the artist is too often weak or unthinking enough to accept.

Hebrew Art.

Whatever arts the Israelites may have originally possessed, it was obviously the policy of Assyrian and Roman conquests to annihilate. It must, however, be recollected, in considering Hebrew Art, that the great incentive to Art-study was wanting to the Israelite. Forbidden, by Divine command, from employing it on the noblest objects and for the highest purposes, Religion, which in other countries enlisted and almost engrossed

the artist's assistance, in Judæa rejected his aid; and thus deprived of its patronage, and excluded from its service, it is not surprising that no school of Art should have been formed worthy of a nation which, by its poetry and its music, has established a character for all time. The knowledge necessary for the production of the Tabernacle and its furniture (entrusted to Bezaleel and Aholiab) may be partly ascribed to the influence of types suggested by the Court of which they had so long been subjects. Of painting we hear nothing. The embroidered works which are described to us suggest an hypothesis of no great extravagance. Their execution implies a previous design—the possibility of supplying which is established by the present existence of such pictorial examples as were produced in Egypt three centuries before that time. It is then not too much to assume that they may have called into requisition for their embroidery such coloured designs as were necessary to furnish the worker in blue, purple, scarlet, and fine linen with the patterns for his occupation. Embroidery was an early form of the pictorial expression. Tyre and Babylonia were celebrated for their works of this kind; and although Homer, so explicit in his descriptions of sculptured shields, is silent on painting, he particularly describes the productions of the needle. That early display of chromatic art was, by a curious coincidence, among the latest suggestions and incentives to the production of some of the noblest creations of one of the greatest minds the world ever saw—for the cartoons of Raphael were designs to be elaborated through the instrumentality of the embroiderer's skill. That the adequate amount of native talent did not exist when, in the height of Jewish prosperity, it was sought to execute a most important work involving multiform considerations of fine-art character, is made apparent when King Solomon, in seeking to realise the plans which his father transmitted to him for the construction of the Temple, found himself necessitated to apply for assistance to a neighbouring monarch. The solicitation itself is an admission made by the Hebrew king, that his native resources, either in material or skill, were inadequate to the importance of his task—while the reply of Hiram is eloquent of the great degree of refinement to which the several arts had attained among the Phœnicians. The extent of their maritime and commercial enterprise is strikingly made known in that chapter of Ezekiel which predicts the fall of their capital. The Phœnicians are known also to us through the page of more modern history, and could our own coast speak, it would be eloquent of their frequent visits.

Theories of Modulation.

It is a curious circumstance, as illustrating the practice of architecture by the Athenians at the best period of their art, that while one finds that a system of allotment of dimension to architectural parts by scale in each building is coherent and consistent, it was in no wise empirical, since another structure erected at much the same time and in the same style will equally have its parts coherent and consistent amongst themselves and yet diverse in certain respects from the contemporary monument. With the Romans, and still more with the Italians, in the revival of Roman architecture the system of allotment of parts by scale, based upon the subdivisions of the lower diameter of the column, or what is known as the subdivision of the module, became no longer elastic, as it had been with the Greeks, but dogmatic. The most accomplished architects fought during the sixteenth century over what may be called the true theory of modulation applicable to each of the five Orders, but all their efforts tended to the establishment of each man's canon as the infallible and inflexible canon of universal application. What was originally then intended as an assistance to the architect, became only a prison and strait waistcoat for him. Such scales of proportion, however carefully devised, produced monotony and constant feebleness in architecture, and only tempted the enthusiastic, who broke away from too strict confinement to launch out into excesses, by which any excellences the system may have possessed were utterly thrown to the winds and lost sight of. To this tendency to rebel against constituted authority much of the extravagance which in Italian architecture became introduced successively through Michel Angelo, Bernini, Borromini and others, may be considered as due.

Vitruvian Proportion and Perspective.

Vitruvius lays down some rules used by the most celebrated Grecian artists, taken from their own writings, for the symmetry or proportions of the human figure and also the geometrical figures which circumscribe its general form and motion. He says, "if a man lies on his back his arms and legs may be so extended that a circle may be drawn around, touching the extremities of his fingers and toes, the centre of which circle shall be his navel;" also, "that a man standing upright, the length of his arms when fully extended is equal to his height." Thus, that the circle and the square equally contain the general form and motion of the human figure. He also says, "the human figure is eight of its own heads in height, or ten faces

from the chin to the growing of the hair, each face containing three equal parts." From these hints and some others in his work, with some also given by that philosopher and painter, Leonardo da Vinci, in which he has pursued the same profound mathematical train of reasoning, a complete system of proportions and motion may be laid down upon the ancient Greek principles. Concerning the optics and perspective of the ancients he has the following passage:—"Agatharcus, of Athens, made a tragic scene under the direction of Æschylus, and left a commentary upon it; being instructed by that, Democritus and Anaxagoras wrote on the same subject, in what manner the extension of rays to the point of sight, by an appointed centre, should answer to the lines by natural reason, so that the certain and uncertain images of buildings should be rendered in appearance by painted scenes, which should be viewed in front on the perspective plan; so that some should retire and others come forward." This passage appears to contain as much of perspective as was known to the ancients, and amounts to this—that rays from visible objects meet in the eye as a centre, and that objects should be represented prominent or retiring, according to their proposed situations. This is certainly all the knowledge of perspective shown in the ancients' works of art, however excellent in other respects; and indeed, from the imperfect description of the eye given by Hippocrates, we have no reason to believe that the nature of vision or the science of optics were much understood when Agatharcus, his contemporary, wrote his commentary on perspective.

A Gothic Revival.

If we consider Gothic architecture to be one of the creations of a great national spirit, we shall at once account for the difficulty of reviving or reproducing it. The Gothic mind aims at constant progression, is not satisfied with retracing steps already trodden; it will not work readily in the trammels of imitation, it will rather attain new glories than strive to recover those that have passed away. We shall find that we have great architects as well as great masters in every other branch of art, if we do not suffer them to be cramped with needless restrictions. The old spirit is not dead in us, nay, it never was more active. Research scarcely owns a limit; science has unveiled marvels surpassing the fictions of Northern mythology; a summary of its triumphs would now be a puerile declamation on familiar facts, as it would formerly have been thought to be upon impossibilities and absurdities. The higher our aims the fairer is the prospect of success. In every other matter, while we honour and value the works of our predecessors, we make use of them as the groundwork of further acquisitions; we continually build upon them instead of merely striving to attain to the same elevation. If a system becomes obsolete we do not attempt to revive it unless we find upon examination that a recurrence to it will give us a fairer start in the pursuit of truth. Our reverence for great names does not make us look at any perfection hitherto attained as a standard or limit, it rather urges us on to a higher perfection; we feel that all we have done in science and art is but an advance towards the truth, not a realisation of it. We may indeed start anew from a given point, if by so doing we may hope for new and great results, but this is a very different thing from taking as our standard of excellence some point that has been already reached. It is true that the desire of improvement and progress has often led to decline and fall; the movement may for a time be downwards, but not backwards; the Gothic mind cannot, in its very nature, be either stationary or retrograde. It is because we have Gothic blood in us that we cannot revive Gothic architecture.

Bayeux Cathedral.

Though it is a composition of various dates, thrown together in a sort of casual way, and though the details of the two towers do not exactly agree, yet the different stages of the front of Bayeux Cathedral are worked together so as to produce a very striking effect. The later work seems not so much to be struck upon the earlier as to grow out of it. One could hardly have thought that spires, among the most elegant of the elegant spires of the district, would have looked so thoroughly in place as they do when crowning towers, the lower parts at least of which are the work of the famous Odo. There is nothing of that inconsistency which is clearly marked between the upper and lower parts of the front of St. Stephen's at Caen. The interior of the cathedral, besides its spaciousness and grandeur of effect is attractive on other grounds. Many facts in the history of Normandy are plainly written in the architectural changes of this noble church. The most interesting portion, indeed, does not appear in the general view of the interior. The church of Odo, the church at whose dedication William was present, and which must have been rising at the time of the visit of Harold, now survives only in the crypt of the choir and in the lower portions of the towers. The rest was destroyed by fire, like so many other churches in Normandy, during the wars of Henry I. Of the church which then replaced it, arcades of the nave still remain. No study of

Romanesque can be more instructive than a comparison of the work of these two dates. Odo's work is plain and simple, with many of the capitals of a form eminently characteristic of an early stage of the art of floriated enrichment—a form of its own which grew up alongside of others, and gradually budded into such splendid capitals of far later work as we see at Lisieux. A striking contrast to the work of Odo—a contrast as striking as can easily be found between two things which are, after all, essentially of the same style—is to be seen in the splendid arcades of the nave, one of the richest examples to be found anywhere of the later and more ornamented Romanesque. The arches are of unusual and very irregular width; the irregularity must be owing to something in the remains or foundations of the earlier building. They are crowned, however, not by a triforium and clerestory of their own style, but a single clerestory of coupled lancets of enormous height with the faintest approach to tracery in the head. The effect is striking, but certainly somewhat incongruous. The choir is one of the most beautiful productions of the thirteenth-century style of the country, always approaching nearer to English work than the architecture of any other part of the Continent.

Polychromy of Sicilian Temples.

Among the earliest Greek works known to us are the temples of Selimuntum, in the south of Sicily. The colony was founded about 650 B.C., and was destroyed in 409 B.C. In the earliest of the temples there can be no doubt that there was colour, from the fact that the metopes are painted. There are also very distinct remains of colour in the other temples. The Duke of Serradifalco, in his work upon the temple of Selimuntum, says:—"The excavations carried out in the temple E and the ædicule B of the Acropolis gave new and more evident testimony of this sort of ornament. There remains of the first many trunks of columns coated with the finest white plaster, and one of them still retains three horizontal zones, each of which is successively painted with red, white and blue. The lintel of the architrave is red, that of the guttæ blue. The triglyphs are painted blue upon the face with black channels. The astragal (?) of the capitals red; and to the posticum of this temple belong certain mouldings in terra-cotta of a yellowish colour, with frets and other ornaments painted in red and dark grey. From various fragments we learn that, as in the Parthenon, the ground of the metopes is blue; and upon the arm of a female figure one discovers some traces of red, which colour as well as blue is much more clearly discoverable in a fragment of drapery found in the posticum of this temple. Nor should we here omit to mention the very singular circumstance that we find the cap of one of the triglyphs first painted red upon the stone, afterwards coated with stucco, and at last repainted with the same colour. We have more important remains of the ædicule B, namely, the trabeation of the south-west angle, one of the lions' heads of the cymatium, in which there remains still the sinking prepared to receive it; one angle and various fragments of the pediment, the whole cap of the ante, the lower portion of the shaft of a fluted column, with part of its Doric cap, and several fragments of minor importance. From the observations made upon these remains we find that the whole fabric was coated with a very fine stucco of a pale yellowish colour, the lintels of the architrave, of the bed-mould, of the corona, and of the mutules; the last blue with white guttæ, blue also are the triglyphs and their fascia, which is divided into two by a very fine line. The capital and what remains of the ante is of a yellowish tint, and all the sunk lines are marked with a fine black line, so as to give more effect to the other mouldings." M. Hittorff goes much further. Indeed, he does not pretend to confine himself to the facts found in the ruins of this temple, but unites fragments and authorities from other temples in Sicily and elsewhere to produce his ideal of the Greek system of polychromy. The Temple of Jupiter, in the island of Egina, supposed to be about forty years earlier than the last of the temples of Selimes, still shows very clear traces of colour. The best authorities have established that the triglyphs were painted blue, the tænia red, the mutules blue; their fillet and the rest of the soffit of coronæ red; the cymatium enriched with a honeysuckle in gold; several mouldings and the soffit of portico painted, &c. There is no evidence that the broad surface, the shaft and caps of columns or the wall of cella were painted. The large patches of blue presented by the triglyphs appear crude and unhappy, and little in accordance with the refined taste of the artists of Egina, but we find an explanation of this in Vitruvius, where he tells us that in the early wooden constructions the ends of the beams (the triglyphs) were covered with a board painted with blue wax to preserve it from the action of the weather; and, as we find in other temples where there are traces of colour that the triglyphs were likewise blue, it is clear that this ancient practice was carried into later times, as a tradition which popular prejudice and a religious reverence for antiquity insisted upon preserving. In the sculptured parts there are undoubted evidences of colour; the shields and the crests of the warriors were painted red, parts of their arms and armour gilt, while the tympanum of the pediment was blue.

NOTES AND COMMENTS.

VISITORS to the cemetery of Père Lachaise, in Paris, cannot fail to remember the statue of Baron TAYLOR that stands in a prominent position. He was a busy and benevolent gentleman, who was at one time director of the Théâtre Français, and held other offices. As he was well acquainted with the precarious incomes of some classes in Paris, he founded five philanthropic societies, which were to be supported partly by the subscription of the members and partly by contributions from the charitable. He began in 1840 with one for actors and actresses; in 1843 another was founded for musicians; and in 1844 one for painters, sculptors, architects and engravers. They were so successful that in 1849 a fourth was founded for inventors and industrial artists, and in 1858 the last of the series was organised for the benefit of teachers. The five societies have now a secured annual income of 486,127 frs., which is equivalent to a capital of about 15 million of francs. The expenditure in pensions and in temporary relief has amounted to 9,333,098 frs. It is no wonder so many people appear grateful when they gaze on the white marble statue of the Baron.

THE Cluny Museum in Paris lost its able director, ALFRED DARCEL, on Saturday. It was owing to the tact of M. DARCEL that many improvements in that most interesting treasure-house were effected. Anyone who can remember the condition of the museum ten years ago will be able to appreciate the efforts of the director. From its foundation the collections were invaluable, but by his agency they have been increased and systematised. It was out of respect for M. DARCEL's efforts that the late M. DE BEAUMONT, the water-colour artist, made over his collection of swords, which so many wealthy amateurs were prepared to purchase at a fabulous price. M. DARCEL was a native of Rouen, and was educated as an engineer. But he was more fascinated by the antiquity of his native city than by the modern improvement works, which are, however, of undoubted interest. He gave himself up to archæological research, and so much success followed his labours that he received an appointment in the Louvre. After the fall of the Empire, M. JULES SIMON (the one man in France who deserves to be made permanent Minister of Public Instruction) appointed M. DARCEL to the direction of the Gobelins factory. There his scientific training served him. But in 1885 he was able to secure his transference to the more agreeable office of director at the Cluny Museum. For thirty years he was a most efficient public servant.

It is proposed to hold in the course of the spring of next year a congress in Paris, which will be attended by representatives of the various societies in France that are associated in any way with art, and especially industrial art. The congress is promoted by the Union des Arts Décoratifs. The intention is to form a sort of federation by the aid of which there will be a continuous interchange of objects belonging to the societies that are associated in the experiment. The idea is derived from the loan collections of the Science and Art Department, but at present there is no certainty whether the French Government would approve of such a scheme. The Union is possessed of a most valuable collection of examples, which are practically of little use to anybody, as there is no place in Paris where they can be properly exhibited. These works could, with advantage, be put in circulation among the provincial towns.

AFTER long years of neglect the Austrians have realised that they once possessed a great sculptor named GEORG RAPHAEL DONNER, and last week in his birthplace, Esslingen, as well as in Vienna, they endeavoured to make amends by festivals in his honour. He was born two centuries ago, and was the son of a carpenter. While a choir boy in a monastery he received some instruction in art from a sculptor employed there. Little is known about his career, and his works are his best memorials. Among them are the figures of gods and children in the Mirabell Castle, Salsburg; the seraphim in the Esterhazy Chapel, Pressburg; the angels in the Buda Pesth Museum, which were formerly in a church; his Viennese works, the statue of CHARLES VI. in the Belvedere, the well-known fountain in the Mehl-

markte, and the PERSEUS and ANDROMEDA in the old Rathhaus. It is supposed that DONNER came to Vienna in 1724 and was employed by the Emperor. Afterwards he went to Salsburg, where he worked in the Mirabell Castle. For ten years he remained with Prince ESTERHAZY in Pressburg. Leaving him, DONNER once more turned his steps to Vienna, where he lived for two years. He died in that city in February 1741, and was buried in the Nicolai cemetery, but his grave is not to be recognised. DONNER was evidently a man of genius, who by a sort of instinct felt that the extravagance which was in vogue in his day was out of keeping with the true principles of sculpture, and that simplicity and truth were preferable to the most dexterous freaks. He was happy to find patrons who could appreciate him, but apparently he was not worldly-wise, for he lived and died in poverty.

MARSHAL DAVOUT, who was one of the Napoleonic chiefs, is to be commemorated in a novel but useful fashion. His daughter, the Marquise DE BLOCQUEVILLE, has left 300,000 francs which will be employed in the erection of a lighthouse on some dangerous point of the coast of Brittany. It has been decided by the French Minister of Public Works that the site is to be at Penmarch. The lighthouse is to be of the first class, and electricity will be employed for the illumination. The chief engineers of the "service central des phares" have co-operated in preparing the plans, and M. PAUL MARBEAU has given his aid as architect. DAVOUT received the title of Prince of ECKMÜHL for his services at the battle around that village, which was fought on April 22, 1809, when the united French and Bavarian army defeated the Austrians. He was created Duke of AUERSTADT after his victory over the Prussians on October 14. On the same day NAPOLEON won at Jena, and the simultaneous battles have received a common name and are known as the battle of Jena.

A PAPER was lately read by Mr. A. CAWSTON on street improvements in the Metropolis. It will form the basis of a volume which Mr. STANFORD is about to publish, under the title "A Comprehensive Scheme for Street Improvements in London." It will be illustrated by views of improvements lately carried out in Paris, Vienna, Brussels, &c., and by sketches of some of the proposed improvements in London, besides maps of London and Paris. The author says that one main purpose of his book is to show that, by systematically working to a comprehensive plan, it will be quite possible to completely transform the streets of London, with no greater strain upon our finances than that caused by the spasmodic and feeble attempts at improvement that have been made during the past forty years. The interest in the book should not be confined to Londoners, for the principles relied on may be adopted in other cities and towns.

THE Employers' Liability Bill has been considered by a committee of the Faculty of Advocates in Scotland, and of course it has been found wanting. Reasonable men could not fail to arrive at a similar decision. The committee of the Advocates have not approved of the abolition of the doctrine of common employment. They thought that the secondary responsibility, as it had been termed, of an employer for the fault or negligence of his workmen should continue to rest upon the principle explained in the Bartonshill case—that "where injury is caused to anyone by the negligence of another, and the person injured seeks to charge with its consequences any person other than him who actually caused the injury, it lies upon the person injured to show that the circumstances were such as to make that other person responsible." Workmen in the same grade of employment, and who were actually engaged in the same work, ought not in fairness to be entitled to impute one another's faults or negligence to their common employer, and visit him with the consequences, if in point of fact he had not been guilty of any fault or negligence towards them. The committee were accordingly of opinion that the total abolition of the doctrine would involve an unfair extension of the liability of employers, and they did not think it would tend either to increase the regard of workmen for their mutual safety or to promote the employers' care for them.

THE COTTAGE, N.
B. VAUGHAN

INK PHOTO. SPHACILE & CO. 4 & 5, EAST HARDING STREET, FETTER LANE, E.C.

Chie Architect, June 2nd 1893.

UNITED PRESBYTERIAN CHURCH, WEST CALDER, N.B.

JAS. G. FAIRLEY, F.R.I.B.A., Architect.

ILLUSTRATIONS.

THE COTTAGE, WALTON HEATH, SURREY.*

THIS is an addition to, and rebuilding of, an old house. The materials of the new part are red bricks and tile hangings, the stonework being in Monk's Park and Corsham stone. The joinery in the hall and billiard-room is in oak. The architect was Mr. B. VAUGHAN JOHNSON, M.A., and the contractors were Messrs. SYME & DUNCAN, of Beckenham.

UNITED PRESBYTERIAN CHURCH, WEST CALDER, N.B.

OUR illustration shows the village church which has been built from the design of Mr. JAS. G. FAIRLEY, F.R.I.B.A., architect. A water-colour drawing of it was exhibited in the Royal Scottish Academy this year.

NEW COMMERCIAL PREMISES, LIVERPOOL.

THIS building is proposed to be erected in Water Street, Liverpool, and will be adapted for large, well-lighted offices suitable for shipping firms. The staircase, which is to be of stone and of circular form, encloses a hydraulic passenger lift. The walls of corridor and staircase will be tiled. The front elevation is to be of Cefn stone, with granite bases. The architect is Mr. W. AUBREY THOMAS.

* From a photograph by Messrs. BEDFORD LEMERE & Co.

ARCHITECTURAL ASSOCIATION SOIREE.

Production of a new and original Medley, in a Prologue and Two Acts, by Theo. Moore and Ernest Rüntz. Played for the first (and last) time at the Westminster Town Hall on Wednesday, May 17, 1893.

"MYTHOLOGY RUN MAD; OR, LES CHUMPS DE MARS."

[BY A CORRESPONDENT.]

(Concluded from page 338.)

ACT I.

THE first scene in the planet Mars shows a rampart of the Acropolis with the bay in the distance, on the shores of which are seen a Greek temple with the Eiffel Tower and a regulation pier. Venus, as a statue, was in the foreground. The presence of the Parthenon in Mars is explained by Pheidias, who thus addresses Zeus:—

I am old,
And Pericles would not with ooftish part,
So here I brought it piecemeal in a cart.
A music-hall I mean to have it now,
Instead of a psalm-smiting shop for thou,
So take some shares.

Zeus declines to take shares, and Pheidias then sings:—

(Air—"The Swanee River.")

PHE.: Way down in Athens I shall never spend happy days;
There's where my temple stands for ever, 'neath gen'rous Sol's bright rays.

All up and down the whole planet-ation sadly I'll roam,
Seeking the sculpture of my own creation, far has it gone from home.
Oh! the walls look sad and dreary, bare the tym-pa-num,
And my lovely frieze of Grecian gee-gees rests in a mu-se-um.

Venus descends from her pedestal, and dances with infinite grace and abandon "a modern dance"—that is, a skirt dance.

Then Sir Christopher Wren and Gwilt enter and discuss:—

WREN. We are at issue about the Parthenon freize. I hold they represent a procession in honour of Athena.

GWILT. And I say they represent the Lord Mayor's Show, and can bring Germans and Americans to prove it.

PHEI. Well, as I, Pheidias, had something to do with it, perhaps you will allow me to say that Sir Christopher's right.

GWILT. Oh! you're mistaken. We have discovered a lot since your time. We change the plans of the Acropolis once a week. You evidently haven't read my book on the subject, ch. 4,021, p. 39,684.

PHEI. I have been spared that honour.

SIR CHRISTOPHER WREN.

(Air—"The Flight of Ages.")

I built a church, a Queen Anne church,
Two centuries ago,
When labour was much cheaper
And the price of stone was low,

And so long as Home Rule's averted
St. Paul's will stand in state
Quite safe from old . . . 's hand,
And poor St. Olave's fate.
There lived a king—Charles was his name—
I served him years ago.
Surveyor-General he made me.
(Architects would call this low, (Aside):
Infra dig. and non-artistic, they'd say he's on the make,
But surveyor notwithstanding, my buildings take the cake.)
(With pride.)

I've had the hump these last two years
Through watching earth afar,
For artists are not as of yore,
And greed and quarrels mar
That which in former years was deemed
A tenet and a part
Is absent, and the charm has gone
For brotherhood in art.
It is a link which seems to me
Should bind us soul to soul.
Shall bitter words much longer hide
From view the common goal?
Memorialists may sniff and sneer,
And Institutes may bray,
But for Auld Lang Syne and Art's advance
Just put this feud away.

Presently the Lightning Streak Express arrives with the A. A. party, under the guidance of Mercury and Cupid. Introductions and flirtations ensue, and then the subscription list opens for the Royal Parthenon Hall of Varieties. All have shares except Cocktail, who decides to "come in in the reconstruction."

ACT II.

The second act opens on another part of the rampart, the Parthenon columns and steps being seen in moonlight. Josephine enters and sings.

Zeus and Mrs. Moriarty, Venus and Leonard, form a couple of pairs of lovers, when the Arcadian love scene is interrupted by a wrangle across the footlights between the authors and the conductor of the band, so realistic in character that many of the audience start for their hats. However, it's all in the book, so harmony is restored, and Leonard sings a new and original song (written and composed by Mr. Rüntz).

SERENADE. LEONARD.

(Air—"Since I first met Thee.")

I.

Since I first met thee, now long years ago,
Thy presence in my soul hath ever dwelt,
And with the years thy form doth dearer grow.
Mine eyes, when meeting thine, now melt with tears of love.
And with the years thy form doth dearer grow,
Mine eyes, when meeting thine, now melt with tender tears of love.

II.

And after weary waiting, though 'suaged the time
By fitful glimpses of thy dear, sweet face,
I now can clasp thee to this heart as mine,
And of the weary waiting time there is no trace.
I now can clasp thee to this heart as mine,
Forgetting all, so great the joy, so great the joy of thee.

III.

May we for ever, linked in bonds of love,
Enjoy the pleasures due to constant hearts.
Awake at last, we pray that Heav'n above
Approves, and death that parts asunder pass us by.
And if, perchance, when looking in thy face,
A cloud should rise, that I have one regret,
Then fold me in thine arms, in fond embrace,
And bid me bless the day, the day we ever met,
Then fold me in thine arms in fond embrace,
And bid me bless the day I met to love and cherish thee.

Zeus then enters and announces that the company is floated and a rehearsal follows by the Sisters Jilt'em (Mercury and Cupid), who dance and sing in capital burlesque of music hall style.

Duet and Dance.—MERCURY and CUPID as the Sisters Jilt'em.

(Air—"Dada wouldn't buy me a Bow-wow.")

I.

We love to twirl our tootsies and to kick towards the sky,
We are the rage upon the stage. McDougall says, "Oh, my!
I cannot stop these naughty chits from flinging high their toes.
What Mrs. M. would say to them—well—goodness only knows."
For we sing old Jimmy Fawn's song of Ju-jah, of Ju-jah,
And Lottie Collins' lunatic Ta-ra-ra, Ta-ra-ra,
"Where did you get that hat?"
And such famous songs as that,
With choruses composed of Tra-la-la-la,
(Repeat) And the chorus ends with tral-la-la.

II.

To Covent Garden Balls we go, high jinks they there allow,
And frequently we end the dance by joining in a row.
The language that we scatter is enough to raise the roof,
The Johnnies seem to like it—and—we're sure we like their roof.
So with simple little songs such as Bow-wow, as Bow-wow,
We entice and mash all comers till they vow-vow, they vow-vow.
They'd love with us to chat,
At the stage-door on the mat,
But of course Mama such things will not allow-low.
(Repeat last line) Which of course Mama will not allow.

III.

So if by architectural work you cannot pay your way,
Well, chuck it out, take to the 'Alls, large salaries they pay;
With cheek and with a voice like bricks to shout out vulgar rot,
You're sure to please and at your ease will scoop a blooming pot.
To the Dog's Home you must go and learn to Bow-wow, to Bow-wow,
There's a lot of "actuality" in Bow-wow, in Bow-wow.
Should your friends shout "Cave canem!"
And chuck mud, you mustn't blame 'em;
Quite classy is this song of Bow-wow-wow-wow,
(Repeat) For it pays to sing the song Bow-wow.

Another "turn" is rehearsed by Mercury as Gravelldow, the strong man, in which the posturing and affectation of this kind of "artiste" are excellently satirised.

After this business the trial of the divorce case, *Zeus v. Venus* (Leonard Aloysius co-respondent), comes on. Zeus as plaintiff, being prevented from sitting as judge, Cocktail is elected to that position; but, before proceeding with the *cause célèbre*, takes other minor cases. First, *Moriarty v. Gwilt*. "Murder of Moriarty's first husband. Deceased met his death by reading prisoner's book when sober." The trial is sharp and short, and Gwilt receives sentence.

Wyatt Papworth is your doom, him shall you revise,
And make your book less valuable and twice its size.

The next case is an ancient-light action, and the position is explained by Gwilt thus:—

There is a bitter warfare
Now raging down below,
And noodles blink and sling their ink,
And mud and curses throw.
But Artists in Art's service
Did not so scarp and scold,
Nor snarl and bite, nor yell and fight,
In the brave days of old.

Then none was for a faction,
Then all were for their Art,
Then the Craftsmen helped each other
And heart communed with heart.
Then jobs were fairly portioned,
Then all were in one fold,
Oh! Architects were brothers,
In the brave days of old.

Now Surveyor is to Art-man
More hateful than a foe,
And Surveyors bite the thumb
And the Art-men scream and crow.
And hot in these polemics,
In working we grow cold,
Wherefore men build not as they built
In the brave days of old.

This case is dismissed, and then comes the great trial of *Zeus v. Venus*, which Pheidias thus introduces:—

SONG. PHEIDIAS.

(Air—"I heard a Voice.")

I.

I heard a case long years ago,
A case where "wifey" tried to show,
With tearful eye and ruby nose,
How she and "hubby" came to blows.
Said she: "He comes home late at night,
And frequently is hoodman, quite;
He whispers huskily, 'My shlove,'
And from the mat declines to move.
Oh! my Lud, he riles me so,
My heart with grief will overflow;
And oh! my Lud, just bid him go,
Please change him for another chap I know."

II.

With Ancient Lights the Courts down there
Expend much time, and light and air
Oft leads to affidavits bold,
Composed of "whoppers" I've been told.
Oh! Architects, more careful be,
Cling to the truth, forget the fee,
Integrity and right uphold,
Your character prefer to gold.

Oh! Architects, I'd have you know
That to a place most warm you'll go;
If facts you stretch a case to prove,
With lawyers there (*points down*) you'll go, and not above.

Zeus gets ten shillings or fourteen days, and in revenge brings a thunderbolt on to the Parthenon, when the columns and walls fall and the steps are heaved up, and chaos and thunder reign.

The various parties endeavour to mollify the irate Zeus in a quintette:—

We feel, oh! dear, the end is near. Mighty Zeus we all distrust;
These verdicts have displeased him, and this show he means to bust.
Oh, Zeus! great host, on our knees we implore that from this you will refrain,
And never, ah! never, shall Architects roam to this beastly star again.

PHEIDIAS. Ah! never, ah! never, shall Architects roam,
ALL. Never again will roam to the planet Mars again.

Zeus relents and all is peace. The A.A. have had enough of Mars and back return singing.

SONG. SIR CHRISTOPHER WREN.

(Air—"Glory and Love to the Men of Old.")

I.

Glory to those Architects of old,
Whose sons have copied their virtues bold,
Courage with Art and with pen in hand,
Ready to work and ready to vie a Master's hand.
Chums—we're willing to dare every chance that's known.
Competitions, if fair,
Are the field for some,
We for premiums try and we won't be last;
Altho' but by one, a job can be won, a place gives us caste.

Chorus.

Glory to all Architects of old!
Boys, strive to copy their virtues bold,
Jealous of Art, surveys we will not eschew.
Ready to fight for linking the two.

II.

Now to accomplish fame,
This controversy's fiery strife should be all over,
Lest—and Architects should toil as tho' its glamour ne'er had come,
Many a student here is waiting anxiously and vainly to discover,
And many a heart must fail and brow grow pale,
To hear memorialists adjure us to succumb,
But don't bemoan,
Surveys we own,
Help keep our home,
But art alone
Gives

Chorus.

Glory to Architects new and old!
Our sons shall not be left in the cold.
Courage! we'll surveys and Art enlist,
And ready to work we'll try to exist.
This rot about Art won't be missed,
Much less a memorialist.
We're ready to work to exist.

FINALE.

(Air—"The Man in the Moon.")

So we'll now bid farewell to old Mars,
For we've seen quite enough of the stars;
As its shores are so bright
You may perhaps think it right
For the A.A. to charge you a bob for the sight.
So now home to your Mama's and Pa's
You may go with our love and ta-tas,
And we hope that we're right
In conclusion to-night
That you relish the trip up to Mars,
You've enjoyed this excursion to Mars.

Jos. enters and sings.

(Air—Chorus of "Man in the Moon.")

I'm in love with this man up in Mars,
He is one of the planets chief stars.
He is quite gone on me,
And I'm sure you'll agree
He's a wonderful help to our Societee.
By the swiftest of railway cars
I've taken this journey to Mars.
There's a terrible dearth
Of young fellows on earth,
But I've found such a nice one in Mars
That I'll marry this man up in Mars.

At end of song exit humming refrain.

Thus ends the play, and so, Mr. Editor, we go home to bed, vastly pleased with our entertainment, but thinking that England, with an occasional turn on the Continent, is a good

enough field for A.A. excursions. Need I say that the show being run by the A.A. Lyric Club, the actors proved an exceptionally strong cast, the parts filled being:—Zeus (a thundering gay old Deg), Mr. F. T. W. Miller; Pheidias (a reformed Memorialist), Mr. A. C. Bulmer Booth; Sir Christopher Wren (warmed up for the occasion), Mr. J. Dixon Butler; Joseph Gwilt (a confounded Nuisance), Mr. F. W. Marks;

Mr. Theo. Moore; Josephine (a *vingtième siècle* party, sister to Leonard), Mr. H. Seton Morris.

The authors are to be congratulated on finding a fresh *motif* for the Annual Play and for the even distribution of fun, life and merry jest throughout, so that the action never once flags, while skilful distribution of light and shade obviates all chance of tediousness. Much praise is due to the stage-

Mercury (a recently deceased Architectural Policeman—Valet to Jove), Mr. P. J. Sutton; Cupid (Page-boy to Venus), Mr. F. Lindsay Sutton; Venus (a study in *confessions*), Mr. Frank Galsworthy; Leonard Aloysius (a Poetic Craftsman, nephew to Mrs. Moriarty), Mr. Ernest Rüntz; Jonathan Gin Cocktail (a Chicago Entrepreneur), Mr. C. H. Brodie; Mrs. Moriarty (of County Dublin, Mother to Venus),

management of Mr. G. Richards Julian and the scene-painting of Mr. Percy D. Smith, whose versatility enabled him also to wield the conductor's *bâton* with capital effect. Our block is from an excellent photograph, taken by Mr. S. H. R. Salmon, of Putney. The electric lighting was carried out in an excellent manner by the well-known firm of William Sugg & Co., of Vincent Works, Westminster, S.W.

THE ARCHITECTURAL ASSOCIATION.

AN ordinary meeting of the Association was held on Friday evening, Mr. H. O. Cresswell, president, in the chair.

House List, 1893-94.

The result of the elections was announced as follows:—

President.—E. W. Mountford.

Vice-Presidents.—W. D. Caröe and E. S. Gale.

Committee.—J. Begg, A. C. B. Booth, H. O. Cresswell, A. W. Earle, F. R. Farrow, Theo. Moore, E. A. Rüntz, W. H. Seth Smith, P. Waterhouse and E. Woodthorpe.

Hon. Treasurer.—H. W. Pratt.

Hon. Librarian.—J. W. Stonhold.

Hon. Secretaries.—F. J. W. Goldsmith and B. F. Fletcher.

Hon. Solicitor.—W. H. Jamieson.

Hon. Assistant Librarians.—C. H. Freeman and W. M. Paton.

Hon. Auditors.—B. Dicksee and G. A. Lansdowne.

Assistant Secretary and Registrar.—D. G. Driver.

Mr. SLADDIN read the following paper:—

Travelling Student's Notes.

Mr. Sladdin said:—Having been awarded the Travelling Studentship, I consulted some authorities, and decided upon Norfolk as my field for operations.

I find when the time comes to read the paper that choosing such a well-known county makes it very difficult to say much that is not already known to most of you, so that you will find this but a brief outline of my tour.

I may say here that my tour was made the more pleasant by having two friends with me most of the time, consequently throughout the paper I am constantly using the plural pronoun we—and I must take this opportunity to thank Mr. Newton for allowing me to add some of his sketches to my own in order to more fully illustrate my remarks.

Norwich was my first stopping-place, and I must say that my feelings on first seeing it were those of disappointment at the insignificant situation the cathedral occupied; it seems difficult to understand why the founders did not select a more imposing site—such as the high ground which rises directly on the other side of the river—in fact, the only spot from which a really good view of it can be obtained is from the river opposite a delightfully picturesque old fifteenth-century archway known as Pulls Ferry. The fine outline of the tower and spire is here seen to advantage, although a closer inspection discloses some hideous detail.

Those who have seen Norwich Cathedral will agree with me that the finest part is undoubtedly the interior. Entering from the west end, which externally is so poor in design, one is at once impressed by the magnificent range of Norman arcading and perpendicular vaulting. The choir, which is of great length, has some exceedingly fine stalls, good examples of fifteenth-century woodwork.

The whole of the east end, including the choir, was undergoing restoration, and I was grieved to notice, particularly in the south transept, that the stonework was being scraped down, and the mellowing effect of ages was being totally destroyed.

In the south aisle of the chancel is a most beautiful font in rather a mutilated condition. The carving in the panels represents the Seven Sacraments and the Crucifixion. The way in which the small shafts are treated, running up under the body of the font, with angels filling up the space between, is very pleasing, and to my mind the whole design is most happy. It belonged at one time to the church of St. Mary in the Marsh, a church that has now been demolished some years. The people of this parish, curiously enough, are allowed to use one of the two chapels in this aisle as their place of worship.

The other chapel in the south aisle is the Beauchamp Chapel, used now as the Consistory Court. It has in it a fine shrine of that period when Perpendicular was at its best.

South of the cathedral, and reached from the south aisle of the nave, are the well-known and much admired cloisters. I have no time in a paper of this length to describe them, but any students visiting Norwich will find them well worthy of careful study.

It may interest you to know that a charge of 4s. 6d. a week is made for sketching in the cathedral. I think this is a case for our secretary.

Turning our attention now from the cathedral. On the upper side of the extensive market-place, and hemmed in on all sides by old houses, stands the fine Perpendicular church of St. Peter Mancroft, restored some years ago by the late Mr. Street. This is one of the few churches in Norwich that is not faced with flint work, and like several others in this district has its clerestory windows very close together, two over each nave arch.

The church has numerous interesting features inside, the

most noticeable one being the baptistery near the north porch, which has lately been most admirably restored by our late president, Mr. Baggallay. The entrance lobby, of which I have measured drawings, is in the south transept, and has a carved frieze unusually fine in design.

In the small church of St. George Tombland is a very remarkable font and cover; the measured drawings which I am able to show you have been kindly lent by Mr. Newton. The outline of the sturdy little granite font gives one at first the impression of its being of pre-Norman times, but the pointed arched heads to the shallow panels on the body of the font, fix its date, I think, to the early part of the twelfth century. The cover is late Jacobean, and seen in perspective the whole thing is exceedingly picturesque. In the church at Knapton there is a font identical in design, though slightly larger.

In the same church is an oak pulpit with sounding-board over; it formerly stood on wooden posts, but unfortunately no trace of these remain, and at present the pulpit stands on a hideously modern solid base. The small staircase has some very delicately moulded balusters; but perhaps the most noticeable point about the pulpit is the ivory inlay, which is profusely used in the panels and soffit of sounding-board. Such work is rare in England at least.

This wooden screen is in one of the chief churches of Norwich, called St. Andrew, Broad Street. The west tower is open towards the nave, and this screen stretches across the opening and reaches from the nave floor up to the ringing chamber in the tower. From the time of the Reformation, and, I believe, until recently, it was covered over with lath and plaster; when uncovered it must have been in a very dilapidated condition, because all the present mullions and panelling in lower part are new, only the old jambs and tracery over remaining. Unfortunately, when the screen underwent restoration, by some mistake its original height was reduced by a foot. In my measured drawing of it the error is rectified.

The chief landmark in Norwich is the castle, standing as it does on a tremendous mound. It is supposed to have been built in 1020, but externally little remains by which one may judge, the whole of the present outside casing being about fifty years old. From the terrace, which runs all round, a good view is obtained of the city, and some idea can be formed of the great number of churches it contains.

In all directions their towers can be seen peeping up above the trees, which abound everywhere. One is immediately struck by the great similarity of design between all these towers, which is still more observable on closer inspection. This sameness, of course, detracts greatly from their interest, and, indeed, a visit to two or three of the forty churches of Norwich will be found amply sufficient to gain a general knowledge of their characteristics.

There are numerous places of interest within easy walking distance of Norwich. Some of these I visited. Thorpe, I think, is the nearest. This straggling village is very pleasantly situated on the river, east of the city on the Yarmouth road. The old hall was built on the site of a bishop's palace, and is a sleepy-looking old house with a very pleasant garden surrounding it. We took a boat here, and by going with the stream for about three-quarters of a mile we reached a half-timbered house, nicknamed by the wherry-men the "Monkey House." It is occupied by the people who have charge of the ferry at this spot, and I thought quite merited a sketch.

Not far from Norwich, but in the north-west direction, and also on the river, is an interesting old Elizabethan house. It was once the palace of Bishop Hall, built in 1587, but is now used for quite a different purpose, being known as the Dolphin Inn. It stands some distance back from the road, with square courtyard in front. The entrance gates are gone, but the large gate piers still remain. I had intended bringing away some record of the front, but unfortunately the weather at the time was not favourable for outside work, and I had to content myself with sketching the ceiling in the bar parlour.

A mile or so further on is the diminutive village of Hellesdon, with a church in proportion, but I saw nothing very noteworthy.

At Costessy, which is in the same direction, but about five miles from Norwich, is the seat of Lord Stafford. I was extremely curious to see the house, as my guide-book laid particular stress upon the beautiful chapel, which was designed by one of the family, but I was not fortunate enough to gain admission. The church, however, well repaid the journey. It is Late Decorated, with good altar-screen and some curious Transitional windows. For a water-colour study it would form a good subject, with its brick tower and wooden spire.

From Norwich we went to North Walsham, which forms a capital centre for reaching such places as Trunch, Knapton and others which have no railway communication.

The only drawing I made in North Walsham was of the wooden font cover which is suspended from a beam across one of the nave arches.

Trunch is a three and a half mile walk from North Walsham, and, as in most of the villages I saw, the church was the chief

attraction. It has a splendid hammer-beam roof, which is so well known as to need no description of mine. The baptistery, which is of wood, is in marvellous preservation, and is certainly one of the best things we saw; it is of very similar character to that in St. Peter's Mancroft.

Knapton is about the same distance from North Walsham, and is famous for not having refreshment for "man or beast." The church itself is like a large empty box, but the roof is exceedingly fine. I attempted a sketch of the roof, but not being very successful, and feeling for once rather slack, and being very near the coast, I walked on to Mundesley, a quiet little watering-place not boasting any railway communication, but I must in fairness say that it is possible to get something to eat here.

The church—St. Mary's—is in a very ruined state, but the tower has been lowered and roofed in, and is now used for service. We had a pleasant coach-ride back to North Walsham.

Whilst staying at North Walsham, we spent one day at Worsted, which is a particularly pleasant walk. The village now is a mere shadow of its former importance, but fortunately the magnificent church still remains a monument to the former wealth and liberality of the Flemish inhabitants. I am sorry to say that the church is now neglected; it is very dirty, and the roof does not fulfil its purpose. I have sketches of the south porch and nave roof, and one of Mr. Newton's of the western screen between tower and nave.

Our next move was to Aylsham, the leading town in this part of the county. The church is of considerable size, and still retains traces of its former interest, in spite of the most thorough restoration:—

You may break, you may shatter the vase as you will,
But the scent of the roses will cling to it still.

In the restoration of the church the upper part of the old chancel screen was removed, and now does duty as a reredos. I am glad to say the lower part still remains in its old position, and is noticeable for its delicate Gesso work. The proportions of the church, to my mind, were totally destroyed at the same time by the introduction of solid backed pews, which are everywhere sprinkled with tasteless carving.

The font is of great interest. The eight sides are filled with sculpture representing the emblems of the Passion, the four Evangelists and the Crucifixion. Carved on the base are the arms of the founder of the church, John of Gaunt, inserted in richly-traceried panels. This font owes its splendid state of preservation to the fact that, until lately, it was hidden from view under a mass of rubbish in one of the aisles.

Another good feature in the church is the ringing gallery under the western tower, which seems to be a general arrangement in Norfolk. This gallery is supported on wooden posts from which spring arches, the spandrels being filled with delicate tracery, and the whole retains its original colouring. The fine old Early English hinges at the western entrance do not benefit by being attached to painfully new doors. The tracery in the windows shows an extraordinary amount of variety, and adds greatly to the interest.

The pulpit is a typical example of Jacobean woodwork, with its panels in false perspective. The stairs are a recent addition, and are the best modern work in the church.

The exterior is a charming example of a characteristically English church, rising, as it does, from the greenest turf, and backed by magnificent cedars. The south porch, which was quite the finest I saw in my tour, is worthy of close study, not only on account of the beauty of its proportions, but also for the refinements of its mouldings.

Aylsham contains more than the usual amount of that delightfully quiet domestic work, the charm of which is largely to be attributed to the hand of time.

The end of my tour was spent at Blickling, which is a tiny village clustering round the gates of Blickling Hall, the magnificent seat of the Marquis of Lothian. No words of mine can convey the exquisite charm of this stately home. The approach to the house lies between yew hedges 15 feet high, which are clipped with marvellous precision. The upper part of this forecourt is flanked by low wings, the one on the left containing the kitchens, and that on the right the stables; these are connected to the house by colonnaded screens.

The house forms an oblong on plan, the corners being accentuated by towers; it is surrounded by a moat, which is now dry and laid out with flower-beds. To enter the house you cross a bridge and pass through a massive door into a small inner court, out of which open the grand hall and staircase, so well known. The iron knocker on this door I have just mentioned is a unique specimen as far as my experience goes. Worked into the design is the Bull's Head—the crest of the "Kerrs"—which also appears in other positions in the building, and forms a valuable precedent for the treatment of armorial bearings in a decorative way.

Proceeding to the first floor, the doors at each end of the gallery, which lead to the State apartments and bedrooms

respectively, are worthy of study. As will be seen in my sketch, the stonework is very cleverly treated, and the carving has a marked resemblance to foreign work of the same period.

The ante-room to which one of these leads is a square apartment, the ceiling of which is more severely treated than any of the others, as will be seen from the plan. The transition from the square to the octagon is skilfully managed. This room is one of those which overlooks the wonderful garden, which, when seen ablaze with flowers, under a summer sun, will not be readily forgotten. This ante-room opens on one side into the State drawing-room, the most noticeable feature of which is the impressive chimney-piece (sketch); the proportion of this is very fine—the rich colour of the woodwork blending very harmoniously with the delicate white of the elaborate plaster ceiling. This room contains a wealth of art in the shape of furniture and portraits of notable people by notable artists.

The other room opening out of the ante-room before mentioned is the library, a noble apartment 120 feet in length, sadly spoilt by the introduction of a rabid Gothic hooded chimney-piece and equally unpleasing bookcases, which do not in the least harmonise with the character of the room. I was informed that to make way for these alterations a splendid Jacobean chimney-piece was removed, which was at once bought by a well-known art collector and re-erected in his own country house. Lately restorations have happily been unattended by such disastrous results. The ceiling in this room is also of marvellous richness, a perfect mine of ideas, the ceiling in each projecting bay window being very freely treated with strap-work ornament, birds, flowers and fruit carved with all that vigorous spirit peculiar to this period when plaster-work probably attained its highest development.

The modern stained-glass inserted in the window at the end of the room compares favourably with much of later date. Before leaving this room mention may be made of the noble collection of books, one of the finest in England, and which are very jealously treasured.

At the end of the library a door leads into the suite of apartments furnished in honour of a visit of one of the Georges, and presenting a most interesting contrast to the sturdy vigour of the other part of the house; being of that weak but delicate style known as the Adam's period, which is so much studied by some of our rising men at present. The further apartment contains the king's bed, and some other excellent pieces of furniture.

To mention in detail the many other features of this fine old mansion would dip too deeply into your time, which I know you require for the pressing business of the evening; but I may tell you that some of the most pleasurable moments of my tour were spent when I was making the sketch of the entrance front. At the close of the afternoon, when the sun slowly sank to rest "and all the air a solemn stillness held," the opalescent tints of the sky, combined with the mellow old brickwork and varied shades of green in the trees and grass, softened in the fading light, to make up a picture infinitely precious to the jaded London draughtsman. At such moments my feelings of gratitude towards the Architectural Association were very lively. My thanks are also due to Lady Lothian for her extremely kind permission to sketch both inside and outside the house.

The interest of the hall so overshadows that of the church that I need only mention the latter briefly.

It was fully restored by the late Mr. Street, who also added the tower. The interior contains some good brasses, and the curious Clere Monument, with its numerous fictitious coats-of-arms.

The late Marquis of Lothian's monument (his reclining figure supported by angels) is a magnificent piece of sculpture by Watts, R.A.; it is a pity that the immense block of marble is veined in places.

The country round Blickling abounds in interest, but I deemed it better to confine myself to the thorough study of one place than to roam about the country getting rapid impressions and making hurried sketches. One Sunday I walked out to see Barningham Hall, which lies in lovely country, and is considered an admirable example of that late seventeenth-century work which has been reproduced with such success by that accomplished architect, Mr. Ernest George. Some distance from the house are the remains of a Late Decorated church, which curiously enough have to be passed through to enter the present church. Walking back I observed the fine tower of Erpingham Church, which I was unfortunately unable to enter. I was astonished to see the name of Cardinal Wolsey on a tombstone in the churchyard, as I had not known that that famous prelate was buried in this out-of-the-way spot. But on further examination I discovered that half the occupants of the churchyard had borne the name of Wolsey in life, and that the "Cardinal" in this case was only a christian name conferred on her offspring by some ambitious mother who wished to render her son immortal.

It was with feelings of regret that we bade adieu to the hospitable host of the "Blickling Arms," who with his charming

daughters did so much to render our stay under their roof an enjoyable one.

Norfolk people, in my opinion, bear off the palm for genuine hospitality. I was everywhere treated with unfailing kindness, and every facility put in my way for the proper study of our noble art.

I have noticed with pleasure that the A.A. excursion this summer starts from Beccles, which is within easy range of the district I have traversed to-night, and I feel that my paper will not have been altogether in vain if it should induce any member who has not already decided to take part in it this year to do so at once.

In conclusion, gentlemen, I have only to express my thanks for the great honour you conferred upon me by giving me the studentship, which, besides affording me the pleasantest of holidays, has been to me an invaluable opportunity of study, and however imperfect my efforts may appear, I can assure you I have striven to the utmost to make profitable use of my time.

Mr. MILLARD proposed a vote of thanks to Mr. Sladding for his paper. He noticed that no allusion had been made to the new Roman Catholic Cathedral at Norwich, the work of a distinguished architect. Possibly Mr. Sladding thought he should confine his remarks to old work. In a sketching-tour Mr. Millard said what to sketch was more important than the actual execution of sketches. The Association did more in the way of architectural education indoors than out of doors. They arranged for one travelling studentship a year. He would like to see a dozen founded.

Mr. WONNACOTT seconded the vote, which was supported by Mr. Newton.

The PRESIDENT put the vote of thanks to the meeting, which was carried by acclamation.

Mr. SLADDING, in acknowledging the compliment, said he had originally intended to refer to Mr. Scott's church at Norwich. The site was a splendid one, the very best in Norwich, but the windows were shallow and the mouldings too much like cast-iron.

PRIMITIVE ART IN EGYPT.*

THE earliest condition of art in Egypt stands in a far different light to that of the history of art in other countries. In the first place, it is as early as, or earlier than, any other source of art that we know. Other countries have largely borrowed from Egypt and from Mesopotamia; but these two great deltas have not had any external influence acting on them; they stood far in advance of the civilisation of the rest of the world in the early ages, and their art appears to be the outcome of the first stable and well-organised governments that were known.

Tranquillity and the command of large resources were needful before any great progress could be made in architecture or the imitative arts; and no land appears to have enjoyed such conditions before the dawn of the historical period of Egypt. We have, then, to deal with a state of things in which art was in course of actual organic growth, free from the influence of any external guidance, and with only its own antecedents to build upon.

In another respect it also stands apart, owing to the absence so far of all traces of its origin and rise. We are still as much in ignorance as ever of the course of its development. Where the tentative stages are to be found which led up to the triumphs of Dynasty IV. is, as yet, a mystery. Certain sculptures, which are undoubtedly very early, have been assigned to Dynasties II. and III., solely on account of the style. But there is no absolute evidence of the date of a single sculpture or a single block before the first king of Dynasty IV., Snefru (the predecessor of Khufu, or Cheops), under whom we find some of the most perfect works that ever were executed. The rise and the course of this art are still buried; and it is only by inferences and side-lights that we can at all estimate what came before Dynasty IV.

In one line, however, there are remains of an earlier style. The rock carvings of Upper Egypt certainly date back to a long prehistoric age; an age when the ostrich and elephant were familiar in Egypt. But these rude figures have no relation to the art of historical times; and we should as soon learn the history of the Parthenon from the weapons of the stone age in Greece as trace the Egyptian schools in the rude carvings of the primitive man.

The oldest sculptures that we know are characterised by being in relief, and by the minute care with which the details of the figures and of the hieroglyphics are wrought. These signs, always in relief, are really elaborate sculptures of distinct objects, and not merely images for an idea—more or less simplified—as they became in later times. This general carving in relief has been very happily explained in connection with the idea of expressing messages or records by means of actual

objects; and from the stage of sending a group of symbolic things, such as a bird, a fish, an arrow, a plant or other real articles, tied or attached to a board in a given order, to the stage of making similitude of them in relief, is a shorter step than the next change, when these carvings become worn down into the expression of mere sounds. Hence the system of these earliest high-reliefs, so elaborately finished, really takes us back to the very origin of writing; and in their completion and detail we see the incompleteness of the great invention to which they led.

Similarly the care, the detail, the lifelike expression of the early figures is due to the sincere belief that as images of the man, representing all that he appeared to the eye, the invisible part of him might then find an earthly home as in his actual body during life. Probably the earliest carvings that we know are the wooden panels from the tomb of Hesi, 4000 B.C. The signs are in very high-relief, elaborately cut, and placed together in inexperienced arrangement. The carving of the figures shows the same care of detail. The muscles are fully modelled and exaggerated, and from the exact maintenance of the expression in these figures the face is clearly a careful portrait. The aim was to produce as exact a copy of the man as possible, without omitting any points which could add to the reality of the image.

Yet we see that a certain model was already established, a model which lasted down to the latest times. The face is fixed, the left leg is advanced, and the manner shows that a settled type had been well practised, and that the idea of variation and choice of attitude was already banished. Hence this, as well as the perfection of the technical work, shows the close of a long time of tentative trials, and a long accumulation of experience.

The first thing that a Western observer remarks on the Egyptian pose is that it is an impossible combination according to our ideas. We see the face in profile, the eye full-length, the chest in front view, and the legs sideways. But before we condemn this as contrary to nature, it is well to see what the nature of a modern Egyptian is, and how far our ideas are correct. To avoid all ideas of posing for the subject, I have selected a figure of a boy from a large group, which was photographed without any special aim by a Cairo dealer. In this kneeling figure we see the profile of the face, the eye full, the chest in front view, and the legs sideways. Everything that we have heard condemned as unnatural and impossible in the ancient sculptures is seen in the modern native, without any constraint, and simply taking an easy position. This shows what is the true idea of the conventional Egyptian pose; it is a three-quarter view, modified by the omission of the much foreshortened parts beyond the profile—a simplification which was essential to an outline system of representation.

The earliest figures which can be dated to a fixed reign are the statues of Rahotep and Nefert, belonging to the time of Senefru. These, as among the greatest treasures of the Ghizeh Museum, may be familiar to many; but they are always worth review, as showing the strength of the primitive work. The lifelike treatment, the exact copying of the real person, the individuality, is so natural that we are almost apt to overlook its art. Yet there is not a single statue of later ages in Egypt which can be put by the side of these without appearing crude and lifeless. They belong to the higher types of race in the country; and the vigour of Rahotep, and the placid beauty of Nefert, are very different from the lower races. In the Queen Mertitefs another type is seen, and a different treatment as well. The physiognomy and the manner are both of them much more akin to the primitive Babylonians; and many links appear between the aboriginal Egyptian and the Mesopotamian, which seem to point to a common origin of arts and ideas. This same character is seen in some early statues at Ghizeh, and the physiognomy has an affinity to that of the well-known scribe in the Louvre. He appears to represent a mixed type, between the aboriginal Egyptian and the higher type of invaders who founded the dynastic kingdom.

Descending a couple of reigns, the next important example of the primitive art is the statue of King Khafra. The front view is familiar in many illustrations, its royal dignity and supreme capacity. But the side view gives a very different light on the expression, we there see the bright intelligence and sweetness of the face without losing any of its nobility. The sculptor has succeeded in combining a most complex expression: august dignity without hauteur or coldness; unconquerable firmness, yet with keen intelligence and vivacity; rigid rule with a winning grace; and monumental gravity with an almost humorous smile. Yet this is the earliest royal figure known, and carved in one of the most intractable materials.

Besides work in limestone, as Rahotep and Nefert, and in diorite, as Khafra, the early sculptors deal with wood in the round with great success. Two of the most vivacious portraits they ever carved are the so-called "Shekh-el-Beled," or wooden man, and the figure of his wife. The latter, which is less celebrated, is perhaps the finer piece. The vigour of the pose, the racy expression, and the whole energy of the work are unexcelled.

* A paper read by Professor W. M. Flinders Petrie before the Applied Art Section of the Society of Arts, and published in the Journal.

The figure of the husband, though excellent, has not an equal inspiration of nature. The best point of view is the front face, and we see in that somewhat the same cast of seriousness that overclouds Rahotep. It is noticeable how, in both of these pairs of figures, the sense of responsibility shows in the man's face; while, in the women, the artist has shown a placid satisfaction in one, and an audacious raciness in the other, without any of the more weighty expression.

This type of face is peculiar to the earliest period of work. Any sculpture of this age is unmistakable in the solidity of its style, and the somewhat heavy but very capable expression. A small statue, now at Bologna, for instance, though without any inscription, could not possibly be referred to any later age.

Besides figures at rest, the primitive people often represented workers engaged in daily tasks. The spirited figure of a woman grinding corn (now at Florence) is almost as lifelike as the more ambitious statues which we have noticed; but the expression is here that of attention to a duty, and not the easy indifference of the other women. Other statuettes represent potters moulding jars by hand, exactly such jars as are found hand-made in the workmen's heaps of the pyramid builders. In these men we see the stolidity of the lower and coarser classes, without any of the intelligence and brightness of the higher people. In the statue of the kneeling servant the aim is that of simple submissiveness—humbly waiting, with folded hands, for his master's orders—an air totally different from the decisive manner of the statues of the superiors.

Besides this class of strictly personal portrait sculpture, the early art also excelled in the lesser figures of the attendants and servants carved in the tombs. The original object of the sculpture was religious, as in the portrait statues. In those, by the exact copying of the external man, the soul was provided with a suitable home; and, by the figures of the servants and animals engaged in all the needful processes of ordinary life, the master was assured of the continuance of all those services for his life in the statue. The sequence of ideas is strictly logical, if we once begin by conceding the utility to the soul of the artificial man—or statue—as a residence; though the outcome of the reasoning and the pictorial provision for all the needs of the body seem incongruous at first sight.

These lesser sculptures, like the statuary, are finest in the earliest periods yet known. The theoretical need of exactness and reality was most felt when the efficacy of the figures was most esteemed; and as time passed a less and less exact and careful treatment was thought equally availing, until the rudest scrawl was substituted for the real image. The tomb of Rahotep, at Medum, from which the lifelike statues came which we have already noticed, contained also some of the finest relief sculptures that are known. The larger figures, and those most within reach, have all been ruinously mutilated in the recent years since the tomb was opened; and, indeed, the only method of preserving monuments that has yet proved successful in modern, as in ancient times, is to bury them safely; no guardian is so efficient as 10 feet depth of loose earth. The upper figures are, however, still in good state, and we there see the triumphant fishermen carrying a huge "fighting fish" hung from the oar between them; the spring of their walk and expression of their zeal are excellent. Another scene, of a herdsman leading an addax, shows an entirely different feeling; here he is coaxing it along, partly by force, partly by favour. In the group of fishers drawing a net to land, the idea is simply the steady performance of a heavy duty; but the man who has sat down in the shade of the lotus to split the fish and spread them out to dry is far more leisurely. The animals are treated with as much expression as the human figures; the elastic prowling walk of the leopard and the fugitive manner of the hunted wild dogs are most characteristic. In another group a little boy is supposed to be in charge of a baboon and a monkey; the baboon has, however, secured the boy's wrist, while the monkey is intent on pulling the tail of a crane in front of him, and is just going to be rewarded by a kick of the crane's leg, which is rising. There are few, if any, ancient figures of animals which surpass these in the vivid sense of their peculiarities and action. One of the most celebrated tombs, that of Tih at Sakkara, which belongs to the following dynasty, is far inferior in the delicacy of the work and the power of expression; and this, in turn, is better than any later Egyptian work. We see then, that in each respect, in statuary, in figure reliefs, and animal sculpture, the earliest work yet known in Egypt is emphatically the best, and has a vitality and realism which raises it far above all later efforts.

What came before this is the great problem. Where did these artists form this style, which—within its limits—is so technically perfect? Where did they acquire this close observation and feeling? When did the preparatory stages come? Judging by what has since passed, there may have been but a short transit from rude and stiff work to this finest period. In Greece how much passed in one century before Phidias! In Italy how great is the step in one century before Botticelli! So in Egypt, a single century may have bridged

the space from cumbrous efforts to the high pitch at which we find the artist, in the first remains which we can date.

But in one direction we can reach back to the art of the still earlier ages of which no actual remains are yet known. The philologist has formed a sketch of the civilisation of races long before all written record, by the evidence of the words and names embedded in their languages. In the same way we may form a picture of the civilisation of Egypt at the age when writing was developed, and when abstract ideas came to be denoted by figures of symbolic objects. This stage of their civilisation cannot have long preceded the time of the earliest art which we have noticed; as, at that period, the style of the hieroglyphic signs was very elaborate, and they were still regarded as symbolic pictures rather than as arbitrary marks for sounds or ideas.

We learn, then, that at the time of the development of the hieroglyphic writing there were more than the mere elements of civilisation; in fact, a high level is in many respects indicated. The chisel and adze were used, made of metal—doubtless copper—and attached to wooden handles. The two-handled plough was in use, as well as sledges for drawing heavy loads. Games were played on portable game-boards. And while writing was yet being formed, the use of signet cylinders of engraved stone, and the scribe's palette and pen-case, all came into use. We learn that industrial arts and organisation preceded the elaboration of the religion, when we see the high priest of Memphis entitled the "great commander of workmen," the high priest of Mendes the "chief of the soldiers," and the high priest of Sebennytus "the warrior." These are the glimpses of prehistoric Egypt preserved to us in the hieroglyphs and titles.

Most happily we have also thus preserved an outline of the prehistoric architecture. The oldest actual buildings known—besides the Pyramids, which stand apart from all later forms—are two temples, that of Ghizeh, built by Khafra, and that of Medum, built by Senefru. The temple of Khafra—the third king whose works are known—is of extreme simplicity; rectangular halls of red granite with plain walls, only decorated outside by panelled work. This has been taken hitherto as the type and limit of the early architecture. The temple of Senefru—the first king whose works are known—is even simpler. There is no granite, only limestone of the neighbouring hills; there is no ornament whatever, only perfectly plain walls, inside and out. From these it might seem that no decorative efforts had yet touched the profession of building, and that construction was not yet an art. But the

OCTAGONAL COLUMN.
(HIEROGLYPH AT MEDUM.)

LOTUS COLUMN AT MEDUM.
HIEROGLYPH FORM AT MEDUM.
COLUMN AT THEBES, DYN. XVIII.

hieroglyphs show how far wrong such a conclusion would be. Contemporary with this earliest and simplest known temple, the inscriptions in these tombs show us that octagonal columns were in use, tapered to the top, and fluted on the sides. These are probably derived from large posts or stems of trees, and are quite as advanced as the well-known columns of the tombs at Beni Hasan, the so-called proto-Doric. Thus we learn that this type belongs to an age when even writing was not yet formed.

Another type of column was also in use, apparently derived from the wooden tent-pole. Being the greatest piece of the tent, it was used in expressing greatness. It has the curious bell top above the lotus flower, which afterwards became developed into the ugly columns of Thothmes III. at Karnak, with a bell capital. This column appears as the central support of a dwelling, in the section view of a booth, which is the hieroglyph for a festival.

Yet another type was in use, with a defined capital. From the banding around the neck of it, it appears to have been first formed of a cluster of some yielding material. Probably it was a bunch of maize stalks tied together, with the tops crushed outward, and then plastered over with mud. It became, however, one of the principal types of the early period; and a row of such columns, seen with the capitals one over the other, became the emblem of stability or firmness. These columns appear in a very curious drawing of a building painted in Dynasty XII.; that shows us a front supported by such columns, crowned with a pediment, borne by a diminishing row of lesser columns filling the tympanum. That this is not merely a sport or stray fancy is certain, from two carvings in the Louvre, one in ivory, the other in wood, which show just such a design copied for small decoration. In the ivory example the window openings in the tympanum are filled with lotus leaves tied together in a manner which is most usual in the Dynasty IV., and it seems not unlikely that this design belongs to the same early period as the first examples of the columns.

All of these types of columns, then, go back to the primitive time of the development of writing, before any of the monuments that we know of as yet. One other feature we can also glean from the same source. The decoration of a cornice with a row of serpents, or cobras, reared up with the hood expanded, was also known in this primitive epoch; and this serpent must already have been used as an emblem before it would be adapted as a symbol on the front of the king's courts of justice.

Leaving this revelation of the unknown age, and coming to the earliest historic period, we find a fourth form of column in use, with a bold capital, a roll at the neck, and a deep torus base. This is sculptured in low relief, on either side of a doorway, but is clearly copied from a column in the round. The source of this form is suggested by a figure of a bowl, placed in a tall, cylindrical stand, which occurs in the same tomb, and which unmistakably resembles it.

COLUMN WITH CAPITAL.

COLUMN WITH
CAPITAL IN
TOMB AT GHIZEH.

The principal remaining type of column—the palm capital—I have not yet found earlier than the Dynasty XII., or about 2500 B.C. Hitherto, it has only been recognised in the Dynasty XVIII., but an ivory carving of the Dynasty XII. shows it completely developed. We can now believe, therefore, that the brilliant granite columns of some temples of this type date back to the Dynasty XII.; and it would be not at all surprising if it proved to be as early a type as any of the other forms of column which we have noticed. The material for it is so abundant and so obvious in the palm groves of Egypt, that it would be strange if it came late in the invention of types. In one point, the palm is among the oldest materials, as the typical cornice of Egypt is derived from the palisade of palm branches, plastered over to form an enclosure, and with the tips left free and curling over, as a fence along the top. Such may be seen now around the courtyard of a peasant, and such was clearly the source of the overhanging ribbed cornice so essential to almost every Egyptian building.

We have now reviewed the primitive art of Egypt, so far as our present knowledge and our recent discoveries enable us to grasp it. The sculpture we, as yet, only touch at its finest development, and the rise of it remains one of the most fascinating historical questions which await solution. The architecture we have been able to trace back to the age of the invention of writing, and we find even then that all the important types of later ages were already in existence. Where the steps which led to this art and this architecture are yet to be found is a mystery. If they existed, in Egypt it seems almost

incredible that they should not yet have been seen anywhere. Some few statues of an extreme simplicity appear to possibly precede those which I have named; but yet there is no trace of any dated remains. Whether the first three dynasties actually reigned in Egypt and filled the centuries assigned to them by later histories may be questioned. Possibly we are to regard the historical lists which name these kings as a rearrangement of materials in the literature two or three thousand years later, in which those lists are first found by us. Some indications suggest that the dynastic Egyptians had not long been in the land before Dynasty IV.; possibly only for a century or two. If so, we might find traces of the rise of their art in some other country; and southern Arabia seems more likely than any other land to have been the source of the conquering race. The Mesopotamian affinities seem rather to be with the aboriginal race of Egypt. Here, then, we must pause, and hope that some happy discovery may enable us to understand in future the source and history of an art which is one of the most perfect and vital of any of the various styles to which different countries have given birth, and which to some extent underlies all the products of later times.

The Acme Wood Flooring Company, Limited.

SIR,—An impression having got abroad that this company is connected with M. C. Duffy & Son, Limited, whose liquidation arrangements have appeared lately in the public press, we shall be greatly obliged by your mentioning in your next issue that there is no connection whatever between the two firms.—

Yours faithfully, H. W. JEFFERY, Secretary.

114 Vauxhall Walk, Lambeth, London, S.E.:

May 30, 1893.

GENERAL.

A Single-Light stained-glass window, depicting *The Resurrection*, has just been placed in Trillick Church, co. Tyrone, to the memory of the late rector. The central figure of our Saviour is treated in a very spirited manner, the light draperies affording a strong contrast to the deep colouring of the sleeping Roman soldiers in the foreground. The canopy and base are unusually rich. The work has been executed for the present rector, the Rev. J. Forde Leathley, by Messrs. Jones & Willis, of Birmingham and London.

Mr. Robert Carey will read a paper on "Economical Hydraulic Lifts," at the meeting of the Society of Engineers to be held at the Westminster Town Hall on Monday, the 5th inst.

The Northampton Town Council have obtained a provisional order for acquiring further land in extension of their sewage farm at Ecton, rendered necessary by the rapid increase in the population of the town. It is to be laid out for irrigation and intermittent filtration, the Corporation preferring this method of dealing with their sewage to the adoption of any chemical treatment. Mr. E. Bailey Denton is the engineer.

A Marble Pulpit, designed by Mr. G. C. Ashlin, R.H.A., has just been completed for Newry Cathedral. The style chosen is the fourteenth-century English Gothic, all the details of moulding and carving being strictly characteristic of that period. The centre panel contains a fine group, the subject being "The Sermon on the Mount." Eight smaller panels contain carved emblems and foliage.

A Design by Professor Gabriel Seidl has been adopted for the proposed Künstlerhaus in Munich. The first stone will be laid on July 8.

Thompson's Cross, at the entrance to Stalybridge, has been restored or renewed according to designs by Messrs. Eaton & Sons.

M. Corroyer, architect, was on Saturday elected one of the vice-presidents of the Union Centrale des Arts Décoratifs.

A Statue of John Knox, modelled by Mr. John Hutchison, R.A., is likely to be erected in Edinburgh, where there is no figure or monument of the reformer.

M. Louis de Forcaud, the successor to M. Taine as professor of aesthetics and history at the Ecole des Beaux-Arts, is known in Paris as a writer of criticism on works of art.

A Local Government Board inquiry has been held at Widnes in relation to an application to borrow 26,451*l.* for improvements. It is proposed to expend 15,516*l.* for work in private streets. It is also intended to expend 10,415*l.* on the erection of a technical school and free library.

The Architect.

THE WEEK.

THERE are not many men in England whose names appear on the lists of selected subjects on whom birthday honours are to be bestowed which would give rise to the general satisfaction with which the name of Mr. JOHN TENNIEL was seen on Saturday to appear on the list. For about half a century the artist has served his countrymen by expressing their sentiments in an artistic form. The history of England and its relations with the rest of the world could be inferred from the figures which Sir JOHN TENNIEL furnished from week to week, if no other record existed. His interpretations no doubt have varied in popularity, for many a time they corresponded with the thoughts of a few manly men rather than with those of the multitude, and the artist was never afraid to rebuke when his duty called on him. His plates are all the better on that account, for they reveal the designer's character. Sir JOHN was always true to himself, and there must be very little which he can wish to erase. He has helped to raise the quality of illustrative art. Many critics have regretted the loss of a great decorative painter in what some may call the caricaturist, and others the cartoonist, for it should not be forgotten that Sir JOHN TENNIEL'S *St. Cecilia* is, in many respects, the most successful of the Westminster frescoes. On the other hand, who can calculate the educational influence of such noble draughtsmanship as he has placed before us every Wednesday? Anyone who compared Sir JOHN TENNIEL'S *Haunted Man* with LEECH'S, when DICKENS'S Christmas story appeared, could hardly fail to perceive that a more exact style of drawing as well as a deeper symbolism was about to be employed, and the promise offered by such early work has been upheld. Sir JOHN TENNIEL'S draughtsmanship has improved from week to week, and his endeavours have been rewarded, for, as yet, signs of decay are happily not evident. He has rendered more valuable services to his country and his age than a hundred Royal Academicians, and yet orators have gone about discoursing on the progress of English art without mentioning Sir JOHN TENNIEL'S name. Was there ever a drawing by him to be seen at Burlington House? The history of his works is by itself enough to show that the Academy is becoming more and more obsolete, for the best efforts of English art take a direction which it can neither guide nor approve, but dare not obstruct.

ALTHOUGH Manchester as a city has aided the Ship Canal with characteristic courage, there is more or less hesitation about undertaking to erect buildings in connection with that great work. This desire to wait until the class of buildings required is demonstrated by experience was revealed at the auction of building sites on the De Trafford Estate, which was held by Messrs. CHINNOCK, GALSORTHY & CHINNOCK in Manchester on Tuesday. Some of the sites were close to the canal. On the first day seventy lots were set up for sale, but only five were sold; the amount received for them was 835 $\frac{1}{2}$ l. As the total area was 13,520 square yards, the price given was only about 1s. 3d. a yard. As the prices offered were insufficient, twenty-three lots were withdrawn. There was no bidding for forty-two lots. At a later time it is probable that a good many of the lots would bring high prices. On Wednesday nine lots were disposed of at a total of 4,165 $\frac{1}{2}$ l., and some building plots were sold, the rest of the lots being withdrawn.

THE Panthéon can hardly be comprised among the modern buildings of Paris, yet only a week has elapsed since the nephew of SOUFFLOT the architect died in the Rue Pierre Chardon in that city. With him passes away a link which united severely classic architecture to the free adaptations of our time. The Commandant SOUFFLOT would in six months have reached his hundredth year, and on that account also was of interest to his countrymen. But his career was in other ways remarkable. As far back

as 1812 he distinguished himself at the battle of La Guarda in Spain, for he was mentioned in the order as having carried off a flag from the enemy. In the disastrous invasion of Russia he was a participator, and until his last days he was unable to forget the horrors he witnessed. After the downfall of the First Empire he remained true to the Napoleonic ideas and withdrew from the army. Subsequently he rendered service to others besides his countrymen by his organisation of the Messageries Maritimes.

THE Italians are beginning to ignore the boundaries of the old principalities as well as the old jealousies, and to recognise as countrymen those celebrities who were born in Naples, Rome, Perugia, Florence, Milan or elsewhere, no matter how much they may have differed in the dialects they used or in the opinions they held. Hence it is that a national subscription has been opened to erect a monument of GIOTTO at Vecchio di Mugello. All Italy should gladly contribute to the fund. Indeed other countries might well share the expense. Who now can think of the artist who superseded CIMABUE as having any local characteristics? His humanity was as wide as it was genial. His great contemporary gave up to party what was meant for mankind, for the poet became subservient to the politician, and the sweep of DANTE'S imagination was often narrowed to suit the rancorous views of the defeated vestryman. GIOTTO'S affection for living beings was too comprehensive to allow him to test the worth of men and women by the degree of their subserviency to his political or parochial notions. As a painter of scriptural scenes and monastic legends he could not avoid introducing figures that were expected to be made unattractive, but even from them we can perceive that GIOTTO was restrained in his hatred. As became an artist, his pencil expressed a sort of universal language, and his works should always have universal appreciation. It is to be hoped the money for his monument will be quickly collected; but if the project should fail, we cannot imagine GIOTTO'S spirit (assuming the intelligence to reach Elysium) would be in the least moved to despise Italy for ingratitude, or even capable of doing so.

ONE of the oldest churches in Brussels, St. Catherine's which stood near the central market, has been removed. It was not a remarkable example of architecture, but as the examples of ancient work are decreasing in the city, the demolition has given rise to some regret among a few archæologists. In Brussels apparently there is a desire to impart the most modern air to the streets, and the value of old buildings in providing effects of contrast is not appreciated. This is one of the differences between the capital and Antwerp. The demolition of St. Catherine's has given occasion to the revival of a subject that has interest for the students of the battles over creeds. ARNAULD, who was one of the followers of Bishop JANSENIUS, was compelled to seek an asylum in Brussels, and it was there he died. The place of his burial was prudently concealed. From time to time researches are undertaken to discover his tomb. M. ALPHONSE WAUTERS has toiled with that view in the vaults of St. Catherine's when they were exposed, but he has been no more successful than his enthusiastic predecessors.

WE have received a copy of the "Tourist Guide to the Continent," published for the Great Eastern Railway Company. It has been compiled for the use of travellers to the Continent *via* Harwich. Holland, Belgium, North and South Germany are dealt with, and attention has been given to providing information in regard of districts of interest unknown to the general run of tourists. The book contains nearly 170 pages, well and copiously illustrated, and a large map. There is much information, too, that is often wished for, but not obtained by those who consult standard guide-books. It is astonishing to find the cost is only sixpence, as it might be split up into some half-dozen guide-books that are offered to the public at a shilling each. The pages devoted to the benefit of cyclists will be appreciated. The guide is specially issued by the company this season in connection with the new route to the Continent *via* the Hook of Holland.

NOTES, PRINCIPALLY ON ENGLISH "GEOMETRICAL DECORATED" WINDOWS.

BY A CORRESPONDENT.

WHATEVER diverse views men may have on the respective merits of the principal recognised styles of architecture, the greatest partisan of, for example, one of the most opposite styles to "English Geometrical Decorated," viz. the Greek Doric, will readily admit that the peculiar beauty of the window tracery of the former period cannot be equalled. Of course there are those who may in this particular feature prefer the *abandon* of the Flowing Decorated, or the stiffness of the Perpendicular styles. But the writer has elected to make comparison with the fenestration in a style where tracery did not exist, and so nothing invidious is intended in the way of vaunting the claims of Gothic above Classic architecture. The number of secular and domestic buildings erected and still existing during the period when the Geometrical Decorated style flourished in this country is certainly very limited as compared with the ecclesiastical work of that date. The reason for this is not difficult to seek and is fairly obvious. The remarks the writer proposes to make are not intended to apply exclusively to church windows, because geometrical tracery of course existed in the secular work of the period when Gothic was the "vernacular" and men built everything in that national style. Wherever square or segmental arched window heads were more handy—in churches, for example, where economy in saving height was of importance, or in other instances—the pointed arch was discarded without any hesitation. For the very essence of the true Gothic spirit was its adaptability to circumstances. The same spirit is to some extent happily exhibiting itself both in ecclesiastical and other architecture at the present day. Architects wisely refuse to be bound by the iron fetters of mere formalism, and this is more particularly observable in domestic buildings. But there is not the faintest idea of advocating in this article any wild eclecticism.

The writer is well aware that window tracery has been ably treated by the late EDMUND SHARPE, E. A. FREEMAN, and others, but the subject presents so large and varied a field that it is perfectly possible to look at it from some other standpoint, and to throw, it is hoped, a little fresh light on the study. It would be foreign to the present purpose to enlarge on the origin of tracery, for that would be a recapitulation of a tale already well told by great authorities now gone to their rest. One of the initial and most important points in designing the windows of a church is to settle the proper width of the lights, so that there may be due harmony and proportion with the building generally, and that they may be neither too narrow nor too wide. When this has been decided, the suitable thickness of the mullions has to be determined. It is surprising what a difference an inch or even half an inch makes, specially when there are a large number of lights, and, of course, proportionately, one-eighth or quarter of an inch makes a great deal of difference in the thickness of the mullions. It is almost needless to say what an important point the depth of mullions from face to glass line is, specially externally. In some of the later windows the "square" from glass line to commencement of the mouldings of mullions is too little, and this results in a poor shallow appearance. In a particular school of architects at the present day the multiplication of lights is fashionable, and so this matter of their width becomes the more important. For it will be apparent that when a three-light or five-light at most was used, the question scarcely arose. Now it is very curious to examine this in the case of Mediæval windows, and to note the immense variation. For it by no means follows that a small village church should necessarily have lights of less width than one of larger size, though, as matter of course, the expected proportion is more usually found. Quite early in his architectural career the attention of the writer was drawn by a friend to the great width (4 feet) of the lights to the magnificent four-light windows of the Chapter-house, Westminster Abbey. Yet these look in good proportion, and it is difficult to realise their real width. It is believed that in English examples this dimension has not been exceeded. In Mediæval Early French one-light windows, the lights are of course often of con-

siderable width, much more so than in this country during the thirteenth century. Of modern architects, perhaps, Mr. JAMES BROOKS has used the widest lights to single windows designed of an early character. In the great traceried windows to the east end of the choir of Lincoln, Carlisle and Ripon cathedrals, Tintern and Guisborough Abbey churches, the widest light is that at Ripon (2 feet $10\frac{1}{2}$ inches). Treating the Westminster Abbey chapter-house windows as exceptional examples, there can be no question that from an architectural standpoint, where the walls are of good and sufficient height and (what is almost as important) of good thickness, the narrow light to a lofty window is the most effective, affording also greater space for internal coloured decoration where that is required. To the glass painter it is true that little scope is thus given for big subjects. But the latter are naturally much more difficult to successfully treat, so this is not so much to be regretted in the majority of cases. Moreover, one cannot have everything in this life, and the true artist can do effective work with single figures on pedestals, with canopies and tabernacle work. Objection is sometimes made to the latter as improper treatment for glass, as representing "sham" architectural details. When one sees the attempts these purists make to give us something better, the result is generally by no means encouraging. To return to the immediate subject. In order to produce their full effectiveness internally, it is essential that narrow lights, especially if single, should have a widely splayed deep internal reveal, and that is why substantial thick walls are so helpful. A church can be just as well, if not better, lighted by comparatively narrow lights instead of by wider ones, and as an architectural composition the result will decidedly be more satisfactory. For the greater number of mullions and the more substantial appearance in the tracery tend to that consummation, while the effect will also be to give greater scale to the building. That is one of the secrets of the architect's success, *scale*, provided he works for it by fair means, without resort to unworthy artifices, such as are to be witnessed in late work in Italy, for example.

There is one important point in the design of a good window that is very frequently quite lost sight of, *i.e.* the treatment of the sills. Take, for instance, the magnificent eight-light east window to the choir of Lincoln Minster, generally considered the finest example in England of Early Geometrical work, any detail of which it seems almost presumptuous to criticise. Everything in it is dignified and according to the best principles, save, perhaps, the sill, which would have been improved if it had been in three or four divisions instead of only two. In the four-light windows to the Chapter-house of Wells Cathedral, far more importance is given to their sills, which are in five divisions, though of course these are on a much smaller scale than the Lincoln example. At Northborough Church, Northants, which is still less in size, the window on the south side of the transept has four divisions to the sill, which is of course very unusual. Even where there is only a single sill, it can be made more effective if of good depth. Again, in cases where for external effect an important looking window is desirable, so as to break up a blank wall-space or for other reasons, the deep window sill or sills is an excellent device, as this obviates the necessity of unduly increasing the amount of actual glass space.

Another important consideration for securing an effective window is to have at least two orders of jamb mouldings. Many elaborate traceried windows lose much for want of this, and have a flat, poverty-stricken appearance. Of course in smaller windows, such as in organ chambers and vestries, the double order is not so necessary. In the opinion of the writer it is better to have a simple traceried window, designed on this principle, rather than a much more elaborate one where it is disregarded. The external label is also a most desirable finish wherever there is room for it, though it can be dispensed with in less important and small windows, as in the instances just mentioned. There is an unsatisfactory mode, by the way, of finishing the label (at the springing line of window arches) when the short "return" of the label mouldings is omitted, as this results in a very crude appearance. Of course a carved boss or a head is a good finish, and prevents the abrupt termination complained of.

The next point for consideration is that very important one of the mullion, for on this depends to some extent the effectiveness of the tracery. It may be stated as a general axiom that it is far better to err, if err one must, on the side of redundant thickness rather than in the other extreme. For one has to consider not only that stone, or possibly granite, in some counties, is the material employed (and so some degree of robustness in treatment may be expected), but that good substantial mullions and tracery aid the construction, both practically and spiritually, so to speak. This, in fact, helps towards that homogeneity in a building so essential to its success as an architectural composition. How many otherwise good windows, ancient and modern, have been seriously injured in their effectiveness by the tenuity of the mullions, &c., which, of course, is more often found in the later than in the earlier examples. No architect should lightly decide on this point without careful study. A great element of dignity in a window is the employment of shafts attached to the mullions as well as jambs. This adds much to the grandeur of the east windows of Lincoln Cathedral, Guisborough Abbey Church, and other important examples.

It was well written by RAPHAEL and ARTHUR BRANDON in that famous standard text-book, "The Analysis of Gothic Architecture," page 26, published nearly fifty years since, "the distinct planes of tracery and mullions thus produced * constitute one of the most beautiful features in Gothic windows." Certainly nothing equivalent to this is found in other styles, and the Mediæval architect "bears away the palm" in this respect. Yet the above axiom is too often disregarded at the present day, when immense windows with elaborate showy tracery are found possessing only one order of mouldings; whereas something of a simpler description, with more subordination of mouldings, would have been far better. In the five-light Flowing Decorated window to the north transept of Nantwich Church, Cheshire, the central mullions are rather thicker than the others, but have the same mouldings. This treatment is not, however, continued into the tracery. The plan is certainly rather unusual, and would, perhaps, be considered by some as daring. But it seems to the writer that it was in details of this kind that the Mediævalists showed the proper spirit, refusing to be bound as if by cast-iron trammels. In this instance the effect is good and emphasises the central light, whereas the adoption of another order to these two central mullions might have raised needless difficulties in the tracery, and involved a good deal more work. This was avoided by the simple expedient just mentioned. Further on it will be shown how at times, when there is sufficient reason for it, deviation from hard-and-fast rules is commendable. In another five-light example—the east window of Houghton-le-Spring Church, Durham—the two central mullions are thicker and a little deeper, without any defined extra order (this extra thickness, &c., being carried up into the leading lines of the tracery), while the central light is wider.

(To be continued.)

THE GRIEVANCES OF BUILDING WORKMEN. II.†

THE trades unionists having been so far successful as to obtain the insertion of clauses in municipal contracts by which sub-contracting is prohibited, they desire to see similar restrictions operating in other matters. One matter which is obnoxious is the employment of machinery in such a way as to become dangerous to workmen. Let us hear what the secretary of the London Building Trades Committee has to say on the subject:—

We think there should be some inspection of builders' premises; we think that the builders' works should be inspected just as much as a textile factory.

Do you mean to say when a building is going on from day to day the Government should provide an inspector to see that the whole of the scaffolding and the works going on there are of a safe character?—No, I do not refer to the building, I refer to the workshops where the work is manufactured. A great deal of machinery—a vast amount of

machinery—is used, and very often unskilled men are employed at those machines and a lot of lads round about, and accidents are very frequent, and there is not sufficient care taken in regard to fencing off this machinery. In the wood-cutting and joinery line there are boys and men engaged on the very dangerous machinery now in use.

Are there any young persons employed?—Oh, yes, persons of all ages.

Steam-power?—Steam-power.

They are inspected, are they not?—Well, it has never been my lot, and I cannot meet with a single individual who has ever known an inspector to come through a builder's workshop. Accidents are very frequent; in fact, two thirds of the machine men now employed in London have lost the majority of their fingers off their hands through the danger of these machines.

That is a very strong statement you are making?—It is a strong statement, but it is the fact.

Two thirds of the machine men?—Yes.

What do you mean by machine men?—The men who work these wood-cutting machines—men and lads; there is generally a man and a boy. Very often in some firms the man is an unskilled man, having no acquaintance with the machine. Not being used to the manipulation of the machines, many a lad is maimed for life; in fact, to show how indifferent some of the workmen become about it, I may mention that I used to know an old foreman in a large mill who thought five fingers were unnecessary on a man's hand, and that if a man lost them while he was young, so much the better—he had got so many of them out of the way. Of course that is simply the cruel way in which it was looked upon, but I do maintain that the builders' shops, the premises where the work is being carried out, should be under close inspection, just the same as factories. Everything should be kept in proper condition and machinery fenced, and every care taken against accidents.

It would be difficult to discover in socialist novels anything more cynical about our modern systems of production than the foreman's remark, but it must not be taken as an expression of the inevitable fate of the attendants on wood-working machinery. Men of that class often become indifferent to their risks, and when they are careless no fencing will protect them. As respects the assertion about the exemption of builders' workshops from official inspection it will surprise many people. The neglect is not caused by any diplomacy on the part of the builders. The secretary of the National Association of Master Builders was asked whether all the workshops were subject to the inspectors of factories, and of course he replied in the affirmative. In his district the officer took care to see that everything was safe, and especially that machinery was protected. If factory inspection is to be advantageous it must be general; and if hitherto the officers have supposed that building workmen are to be found only on buildings in progress they will do well to take a hint from the evidence before the Labour Commission.

Sanitary inspectors in some places are also remiss in their visits to builders' workshops. The following statement by Mr. MOORE, the non-unionist workman, has, we fear, little exaggeration about it:—

In the large and best workshops in London, Cubitt's and other firms of that class, you find things on a very good footing. You find the sanitary condition of the place, and the general rules and regulations very reasonable and fair; but where you find one firm like that you will find a dozen in which there is great indifference and great neglect upon the part of the employer, in whose hands, of course, the matter lies as to the sanitary condition of their workshops. You will find workmen working over stables, with a lot of horses underneath them, and you will find that the sanitary offices and places of convenience are in a shockingly bad condition. I do not think I need go further into the details of that matter, it ought to suffice me to say that they are in a shockingly bad condition, affecting the health of the workmen. Of course, it matters little to the employer; he goes to the shop probably once a day twice a week; at some places not that. His foreman goes down to the office and transacts his business with him, so it does not affect the employer at all, but the workmen are there all day, and they suffer in health.

The dangerous condition of workshops, if general, would be enough to create a grievance. It is brought forward, however, to support a more important contention, viz. that builders are indifferent to the safety of their workmen. This is seen from the assertion of the secretary of the London Building Trades Committee:—"In the building trade I can assure you that the system of allowing the contractor to insure out of his liability simply by paying a small insurance fee does not cause him to take care of the lives of his workmen." That is to say, the builder will not trouble himself about the defects of his plant, by which men's lives are risked, as it is much easier and more economical to cast the responsibility on an insurance society. But the workmen are not satisfied by the arrangement, although Mr. MUNDELA and the economists approve of "contracting with some wealthy insurance com-

* *I.e.* "By the introduction of distinct orders of mullions and by recessing certain portions of the tracery from the face of the primary mullions and their corresponding tracery-bars."—R. and A. Brandon.

† *Minutes of Evidence of the Royal Commission on Labour.* Her Majesty's Stationery Office.

pany that takes the average of accidents all through the country." Is it inevitable that building must comprise the killing and maiming of craftsmen and labourers? The men do not think so, and by their spokesman, Mr. Dew, they say:—"We do not really want compensation for accidents. We do not want accidents; we want a Bill that will practically prevent accidents." The insurance has unhappily become so common, it may appear to be a necessity; but its origin is most modern in the trade, and, curiously enough, corresponds with the time when the new class of contractors arose. It is not so long since builders were acquainted with all their workmen, and that is not strange, for masters and men used to be associated for years. Nowadays, the periods of engagements are brief; there is a constant change, and employers and employed have only such relations as can exist among the elements of "averages." The contests, therefore, over accidents have become more bitter from becoming as it were impersonal. The men have to deal with opponents who are unknown to them, and who appear not as individuals but as a corporate body, without any feeling except the very strongest repugnance against paying damages or doing anything that will affect the infallibility of the average calculations. The workmen observe that the insurance companies do not trouble themselves about the condition of plant and machinery, and they are hardly to be blamed if they conclude that whenever accidents arise the chances are that the companies will escape expenditure on compensation. Mr. MUNDELLA is ready to overwhelm a witness by citing cases of explosions in mines and wrecks at sea as evidence that accidents are inevitable, and that the doctrine of averages must therefore be held in respect. The obtuseness of mind among builders' workmen is of such density that it cannot be overcome by official logic any more than by tracts. The men imagine that in mining and on the ocean there are dread natural forces at work with which we cannot always grapple, whereas in building all dangers can be foreseen and provided for. What is it to them if the averages are found to be exact; if they have to suffer during life through the neglect of some slight provision the accuracy of statistics brings little consolation. It is hard enough to have, out of loyalty, to sacrifice individuality at the bidding of a trades union, without being expected to be glad at becoming a cipher for the use of assurance specialists.

There is another view to be taken of accidents which does not present workmen in a favourable light. There is no doubt men suffer not from the carelessness of masters alone, but also from the maliciousness of their fellow-workmen. The records of the courts reveal too many cases which prove that trade is jealous of trade, and that without scruple acts will be done with the intention of inflicting injury which under other conditions would bring the doers within the purview of criminal law. It is astonishing how liable the workmen engaged by specialists and sub-contractors are to come in contact with falling bodies, and with what ease planking bends under their weight. To those who are not able to see below the surface the declaration of one of the representatives of the carpenters, "we maintain that as the workman has no control over his fellow-workman, however incompetent he may be, the employer should be held responsible for the accidents which may occur to another fellow-workman," will appear to express nothing remarkable, but it really means that there is a mutual apprehension of wilful injuries, and that as it is impossible to reform the men, the wisest course is to make the employer pay for whatever occurs on his premises. It was pointed out by Sir FREDERICK POLLOCK that by common law a man who has suffered injury from an employé or servant can only bring an action against the master of the servant, but what workmen seek is to be put in a better position than any other members of the public, and to have the liberty to bring actions for compensation against whichever party connected with the works is best able to pay.

Whatever the workmen may do, it must be said that little advantage is to be derived by them from accidents. When actions at law succeed the plaintiffs have to settle with the solicitors, and, as one of the witnesses, said, "there is more money goes in costs than the men get." There is no reason apparent that accidents should have assumed so much importance in connection with building. In days when there was little aid to be derived from

machinery, the most difficult operations were gone through without injury to life or limb. In our time the risks are diminished. By the exercise of efficient management on the part of masters, and by a little less selfishness and indifference among the men accidents should be avoidable. For as a carpenter and joiner acknowledged, "In the case of some of the very best building firms in London you rarely hear of accidents, or you hear of very few accidents, indeed, where they are very careful."

The last grievance we may notice relates to the number of hours during which building workmen should be employed. To many it will appear as the most important of all. For instance, one witness when asked how far he wished Government to meddle with business, replied:—"I cannot agree with their regulating wages; I think if the hours are regulated wages will regulate themselves." His answer makes it evident that when an eight-hours day is demanded it is not because the men are exhausted if they work longer, nor that they are anxious to avail themselves of the facilities for technical education, but simply because they hope that a high rate of wages must accompany a brief term of employment. Another witness expressed the same notion when he said: "I generally find in most of the trades I am conversant with, that the longer hours they work the less wages they receive," and he added his conviction that "the shorter the hours men work the more they will receive."

The desire of every architect will be that builders and workmen can carry out contracts with satisfaction to themselves. But it must not be forgotten that clients or building owners have also interests which are in danger of being overlooked. It seems to be a truism that a diminution of the hours of labour must mean a corresponding diminution in the quantity of work that is produced. As the time allowed for the erection of buildings is generally a fixed quantity, it must follow that they will have to be delayed or a larger number of men will be required. In either case the cost of building will be increased. In the present condition of business it is not likely that the public will readily agree to pay more, and the number of new buildings erected will consequently be diminished for a longer or shorter period or until people have grown accustomed to the rise in prices. There is an alternative. Builders are likely to cheapen production by using a still greater quantity of stuff that can be turned out by machines and by giving larger orders to foreign manufacturers. Can architects be expected to condemn that arrangement or any other that will conduce to economy? As one of the workmen who gave evidence before the Commission said:—"Practically, the architects are employers; their whole interests are with their clients, those who pay for the work, and with the employers." They are not without interest in the men also, but when men are prepared to sacrifice builders, building owners and architects, if that would bring them a trivial advantage, can architects be expected to meekly offer themselves and their clients as victims on the altar of trades unionism?

CHELSEA INFIRMARY.

THE following letter has been addressed to the *West London Press* by Mr. H. Young:—

In the recent competition of architects' designs for the proposed additions to Infirmary, and which when built will occupy the corner site of Sydney and Cale Streets, I beg to say that I did not charge Mr. Blore with "jobbery." I solely advocated, on the grounds of fair play, that as seven architects had been invited to compete, and who were nominated by the Guardians, that the proper course to pursue to prevent misunderstanding or friction would be to appoint an independent assessor of standing such as Mr. H. A. Hunt or Mr. J. M. Brydon, both professional men who have acted in a similar capacity on behalf of the parish for respectively our new Town Hall and new Library at Kensal Town, to adjudicate and report on the best set of plans, and if the same could be carried out at the limited cost. The conditions as to cost are set forth at 5,000*l.*, plus an allowance of 10 per cent. as an extreme amount. Now, although I believe Mr. Blore to be one of the most upright and conscientious men in this parish, and one who undoubtedly gives an immense amount of time and invaluable assistance to the local institutions, yet I cannot help sympathising with him for inadvertently

falling into what I consider a grievous error through over zeal. On my going to the General Purposes Committee, held May 17, I found Mr. Blore enthusiastic on a certain elevation drawing marked 3, to which he drew my attention as also that of other members, and he handed me a written report which he said Mr. Brass and himself had drawn out together. This report dealt exclusively with the merits of designs marked No. 3 and No. 2, and which consisted in "The facilities afforded for Ventilating and Heating." All other designs were ignored *in toto*. This appeared to me so childish and ridiculous an argument that I pressed for an assessor, to which Mr. Blore said he would not object. I also sent him a telegram from the country urging this request. I must mention here that one architect declined to submit a design (wise man) for reasons I know not, but this vacancy was filled up by the authors of No. 3, who sent in the design No. 2 without the knowledge of the Board members. Imagine, then, at the Board meeting of May 24, the Assessor ignored, and Mr. Brass moving the adoption of No. 3 for first premium and No. 2 for second premium, and Mr. Blore having much pleasure in supporting the recommendation! The chain of unfortunate circumstances, I consider, consisted of—

1. The architects being the nominees of Mr. Blore.
2. Both designs being by his nominees.
3. By privately submitting a report and canvassing, Mr. Blore apparently assessed for his friends.
4. That Mr. Brass, having moved for a committee to materially alter the structural design by cutting out the towers and turrets at corners of building, tends to show that the work cannot be done for 5,000*l*.
5. That at this committee-meeting, held May 30, Mr. Brass (after his motion was defeated) said the towers would not be permitted by either the London County Council or the Vestry, only shows that the selection has been hastily made, and, if true, should disqualify the plans he so much advocated.
6. That the architects, in reply on heating, said they intended to take the heating power from an existing saddle-boiler in use at the Infirmary for other purposes, and, if inadequate, "a new and larger boiler must be put in at the cost of the Guardians."

So that the heating theory referred to by Mr. Brass becomes a farce, and further comment is unnecessary.

PALESTINE EXPLORATION.

THE following account of Mr. F. J. Bliss's lecture as to the excavations which he has carried out during the last two years at the mound of Tel-el-Hesi, the site of the ancient town of Lachish, appears in the *Manchester Guardian* from a correspondent. A simple diagram on a blackboard explained the position of the stream, which, itself 220 feet above the level of the sea, has its course 60 feet below the bluff upon which the earliest of ten towns successively raised was built about 3,000 years B.C. The mound rises to a height of 60 feet above the bluff, and the theory of its growth held by Professor Flinders Petrie has been confirmed by the investigations of Mr. Bliss. The lecturer showed that the mud bricks of which the towns had been built readily formed a foundation for rebuilding, the process of reconstruction having been carried out in each case at an increased altitude of something like four feet, so that at the building of the tenth town, which was ruined in the fifth century B.C., the present height of the mound would be nearly reached. Mr. Bliss explained that before he began his work there was no sign of any ruin on the mound, which was covered with a crop of beans. His first step was to set thirty men digging, assigning to each a space 10 feet square, with two or three dozen helpers to carry away the refuse earth. The work had not gone on for half an hour before Mr. Bliss plainly saw that he was digging in no ordinary soil, numerous pots, lamps, beads, &c., coming immediately to light. The domestic habits of the people resident in the neighbourhood to-day help to throw considerable light on the discoveries, for they were accustomed to use the same utensils as their progenitors in past ages. The results met with in excavating the second town were better, because the ground was freer from moisture. A burnt barley store was met with at a depth of 8 feet. The explorers found much difficulty in distinguishing walls from *débris*, on account of the nature of the building materials, so much so that Mr. Bliss spent his first month at the Tel in crumbling brick to ascertain its composition. When the third level was reached certain parallel lines of stones with intermediary wallings revealed the site of some large public structure, the stones having formed the basis of pillars built of wood or brick. Thus the work proceeded through six levels, when a bed of ashes was met with 4 or 5 feet thick and 100 feet square. Many days were spent in its removal by 80 to 100 men, until at last Mr. Bliss almost despaired. But at length occurred the

discovery which gave the romantic side to Tel-el-Hesi, in the finding of the other end of the correspondence which had been brought to light in Egypt, including letters from consuls and governors of Syrian towns to the kings of Egypt. The find was made immediately below the bed of ashes just referred to. The tablets on which the letters were written belong to B.C. 1400, and they prove conclusively the use of cuneiform writing at that date between one town of Palestine and another.

At the conclusion of the lecture Professor Flinders Petrie congratulated the society on the co-operation of so able an excavator as Mr. Bliss, who combined in a manner almost unique familiarity with Syria and with England alike, not to mention his scientific acquirements. His method was not to be surpassed for accuracy, precision, and thoroughness of record. In certain other cases an unscientific method of procedure had occasioned fearful losses. But in this instance there had been no loss, while Mr. Bliss had obtained for us through his discovery of arms, pottery, &c., knowledge of an ancient civilisation which heretofore had been to us but a name.

SYDNEY ARCHITECTURAL ASSOCIATION.

THE opening meeting of the 1893 session of the Sydney Architectural Association has been held. Mr. George J. Oakeshott, A.R.I.B.A., president, occupied the chair, and there was a good attendance.

The committee's report recorded the continued success of the Association, as the membership, notwithstanding the depression, stood at 113. A few resignations had taken place, but they had been more than compensated for by the new members who had joined. The meetings during the past session had been held at the Royal Society's rooms, a change from the former meeting-place that was much appreciated. On April 8 last the president delivered his opening address on "The Future of Architects and Art," and other gentlemen had followed with valuable papers, which were much appreciated. The committee regretted that through unavoidable causes the classes were not carried through to as successful an issue as was anticipated, but it was hoped that during the ensuing session members would unite in the determination to make them a success. On May 2 the subscription for hon. members was altered from 2*l*. 2*s*. to 1*l*. 1*s*. per annum. The sessional visits to buildings had been well attended, and it was proposed to make arrangements for a continuation of visits throughout the session. Gratification was expressed at the success of the Arts and Crafts Exhibition, which was opened on October 26 last. The report was adopted.

The President, in his annual address, returned thanks for the honour that had been conferred on him in electing him to the position, and claimed that he had one qualification for the high position, that there was no one who had the interests and welfare of the Association more at heart than himself. They had much reason for congratulation as well as regret; but their weakest point was undoubtedly the collapse of the classes, which from the first had been poorly attended. He attributed that failure to the lamentable apathy and indifference of their young fellows, and an apparent inability for any kind of serious study and application, increased by an inordinate love of pleasure and sport. They had carried on in the past three classes—the elementary, or, as they intended to christen it, the draughtsmanship and design class, the class of design, and the class of construction. He insisted on the importance and benefit of these classes to young architects and draughtsmen, and held that they should prove the backbone of the Association. He referred in terms of pleasure to the success that had attended the Arts and Crafts Exhibition, and said it had conferred a benefit on the community, and had been an educational advantage to the profession. A specially interesting feature was that of having craftsmen in different trades actually at work in the building. The monthly meetings had been an unqualified success, and it was held that members would largely benefit from a full use of the library, which contained a number of valuable volumes. Members would also benefit by visits to works in progress, but he regretted that some of the younger ones did not feel inclined to enter into the competitions on the ground that the prizes were too small. In conclusion, he urged members of the profession to unite and do their best to advance its interests.

Mr. H. Hunt, president of the Institute of Architects, said that one of the weakest features in their training was that there was a great disinclination on the part of students to work for other than monetary gain. The value of a good library could hardly be over-estimated; nothing could be more valuable in their profession than a good library. There was too much laziness amongst the younger members. Surely they should be ready to sacrifice their sports and pastimes for a visit to a good work in progress.

SKETCHES AT ALKMAAR, N. HOLLAND.

THESE sketches are some of a series made in a very pleasant sketching tour in N. Holland during July and August 1886; they are of old work at Alkmaar, an interesting city, though inferior in architectural interest to Haarlem, Leyden, or Hoorn; it contains, however, many bits of characteristic work. The Friesche Poort on the Great North Holland Canal is built more or less after the accepted model—square at the

base, with a lean-to on one side, a steep-pitched roof surmounted by the familiar many-storeyed turret with open top. Opposite the Weigh House, or what is called the Waagplein, is the old house shown in one of the sketches. The lower storey and frieze are cement; the date is 1607; the upper storeys brick. Throughout this part of the country the bricks used are seldom thicker than $1\frac{3}{4}$ inch. During my visit the tower of the almshouses in the Gedempte Nieuwestraat was being repaired; it rises without a break from the pavement to the cornice, and forms a very effective feature.

LAMBETH AND VAUXHALL BRIDGES.

LAMBETH, the *Standard* says, is in trouble about its Bridge, which it considers to be dangerous and in need of reconstruction, whereas the London County Council have passed it coldly by, and proposed to lavish 400,000*l.* on a new communication across the river at Vauxhall, the existing bridge at that spot to be superseded by one of five arches formed of steel, with granite-faced piers and abutments, the width between the parapets to be as much as 80 feet. When all this is done, as provided for by the London Improvements Bill now making its way through Parliament, such ample accommodation will be afforded for the cross-river traffic in that part of London, that a fear arises lest Lambeth should be left out of the reckoning altogether, and it is even rumoured that the County Council contemplate the entire extinction of Lambeth Bridge. So sweeping a measure is incredible, and the apprehension probably has no further warrant than a possible change in the site to a few yards higher up the stream when the bridge comes to be rebuilt, so as to provide for better approaches. In mediæval times Lambeth had its ferry, partly, it may be, on account of the archiepiscopal palace on the Surrey shore. On the Middlesex side we still have the "Horseferry" Road in memory of the past. To extinguish the bridge would be to ignore what must be a positive need for communication across the stream at this point. Lambeth Bridge stands midway between Westminster and Vauxhall, and its abolition would leave an unbridged gap of a mile in length between these two points. A local committee has been formed, headed by the Rev. Canon Pelham, Rector of Lambeth, and Sir Henry Doulton, who intend waiting upon the Bridges Committee of the County Council in reference to the entire subject. We have reason to say, that the committee will learn, although a regrettable delay is undeniable, that there is no intention to postpone indefinitely the claims of Lambeth Bridge. Supposing the necessary authority to be obtained from Parliament for superseding the present Vauxhall Bridge by a new structure, the next step will be to obtain power for constructing a new bridge at Lambeth. There ought to be no more time lost over this matter; but the process threatens to be a slow one. Prior to the pulling down of Vauxhall Bridge, a wooden structure, not less than fifty feet wide, is to be erected across the river from the extreme western end of the Albert Embankment to Millbank, to serve as a temporary bridge, the cost of which is estimated at 30,000*l.*, the estimate for the permanent bridge being 380,000*l.* We understand it is in contemplation by the Council that, after Vauxhall Bridge is finished, this temporary structure shall do duty for Lambeth Bridge, while the latter is being reconstructed. The commencement of the new Lambeth Bridge, therefore, seems to date from the completion of the new bridge at Vauxhall, and it is thus postponed to a somewhat remote period.

Lambeth Bridge was opened in 1862. It is a suspension Bridge with three spans, each 268 feet long. The four wire chains each contain seven twisted cables 3 inches in diameter. There are seven strands in each cable, and seven wires in each strand, making the total of the wires 1,372. The entire width of the bridge is rather less than 32 feet. The breadth of the roadway is 18½ feet, flanked by two footways of 5 feet each. The chains pass through four iron towers, supported on iron cylinders, originally sunk to about 18 feet below the bed of the river. The towers themselves are 33 feet high, and take the form of archways, spanning the bridge from side to side. In each of these arches the base is several feet wider than the summit, the effect being one of extreme ugliness, especially as the iron plates which form the outer skin are painted of a dull brick colour. With these horrid structures straddling across it, the bridge also has the defect of a strange up-and-down curve in the line of roadway from shore to shore. Railway engineers have been long looked upon as unequalled in the construction of ugly bridges, but they never surpassed this one, which stands as a perfect monstrosity, in view of the Houses of Parliament, the pavilions of St. Thomas's Hospital, and the graceful Westminster Bridge. Even the old proverb, which requires that we should speak well of a bridge which carries us safely over, can scarcely be pleaded at Lambeth. Reporting on its condition in 1880, Sir Joseph Bazalgette remarked that the twisting of the wires was a source of weakness. At that date a considerable quantity of rust had been recently removed from the cables, amounting in some parts to nine pounds' weight in a length of five feet, nearly half being pure iron, the structure suffering a certain loss of strength in consequence. The Metropolitan Board had then affixed a notice to the bridge, restricting the load allowed to pass over it to five tons. This Sir Joseph considered to be "a necessary precaution." In 1887 the anchorage of the cables in at least one of the abutments was found to be giving way. In accordance with a report from Sir B. Baker, certain repairs were at once executed, and it was considered that the structure was thus rendered secure for some years to come. But it is evident that the bridge has to be sedulously nursed. The five-ton load

of 1880 is no longer considered a safe weight to be borne. The Council have prescribed that no locomotive or steam-roller shall go on to the bridge or pass over it. The prohibition is extended to a load of any kind exceeding three-quarters of a ton on each wheel. The aggregate weight is in no case to exceed three tons, including the weight of the carriage. At this rate, an omnibus would scarcely be admissible, if full inside and out. How much lower the limit will be drawn is a matter for conjecture; but it has been satirically suggested that by-and-by the rule will become so rigid as to admit of only a man and a boy. The other day, when Captain Boyton had his demonstration on the Thames, the gates of Lambeth Bridge were closed to exclude the crowd, lest it should break down. That such a bridge should exist within the boundary of the metropolis is little less than marvellous.

It cannot be said that the County Council are ignorant of the state of things to which we have referred. Their own regulations as to the traffic show how thoroughly they appreciate the perilous state of the bridge. The committee which recommended the reconstruction of Vauxhall Bridge spoke of the traffic at that spot as having been much increased of late years, not only in consequence of the enlargement and alterations of the railway station in the neighbourhood, but as a result of "the weak condition of Lambeth Bridge." There are returns which show that the number of vehicles crossing Vauxhall Bridge experienced an increase of 50 per cent. between the summer of 1879 and a similar period in 1891. At the same time, it must be remembered that part of the Lambeth traffic was diverted into the Vauxhall current. Concerning the relative state of the two bridges, it may be said that Vauxhall Bridge is sound in its superstructure, though weak in its foundations; while exactly the opposite is the case at Lambeth. That Vauxhall Bridge must needs be rebuilt at an early date may be admitted. As far back as 1878, the foundations were discovered to be insecure, if, in fact, the bridge could be said to have properly any foundations at all. Mr. Law described it as "placed on the bed of the river," simply standing on a timber platform resting on a surface of clay. For the protection of the structure, Mr. Law said he saw no better mode than that which was proposed for Waterloo Bridge, namely, putting caissons round the piers. He considered that the time had arrived when this ought to be done. The bridge is considerably older than the one at Lambeth, having been completed in 1816. The piers are of stone, with a superstructure of cast-iron. Its original cost was 260,000*l.*, and the Metropolitan Board bought it for 75,000*l.* Last year a diver was employed by the County Council to examine the foundations, when it was discovered that the action of the tide was removing the protective works which had been laid down. It was evident that the bed of the river was continually deepening, owing to the great scour caused by the high velocity of the current, which sometimes exceeded seven miles an hour at the surface, and impeded the progress of steam vessels passing under the bridge.

ST. MARY'S SPIRE, OXFORD.

FOUR alternative designs for the repair of the pinnacles of St. Mary's spire were submitted to Convocation on Tuesday by the Vice-Chancellor. After expressing his high sense of the zeal, labour, and courtesy of Professor Case, whose investigations have been lately summed up in a volume entitled "St. Mary's Clusters," Dr. Boyd gave his reasons for preferring the design of Mr. Jackson, endorsed by Mr. Bodley, though not by Mr. Jackson himself. The other design of Mr. Jackson he regarded as of great architectural merit, and if it was a question of building on a new site it would be the one he should select. But, taking all things into consideration, he should vote for plan D—i.e. for the reproduction of Mr. Buckler's design with the pinnacles lowered. To the ordinary untrained eye the cluster would appear unchanged, but the architectural eye would be satisfied. He hoped a plan would be selected avoiding a delegacy with its delays and responsibilities for himself and the proctors.

Professor Pelham said he must vote for a delegacy, as intricate considerations were involved, though he thought their deliberations need not be prolonged.

Mr. William Morris said it would be a pity to refer the matter to a delegacy; one thing was impossible, namely, to restore the fourteenth-century spire. He was in favour of repairing Mr. Buckler's work as the object of his boyish affections. But, further, he wished to plead for certain persons of whom hard things had been said, who were accused of having lost not only their hands but their heads. For these statues he was a thick-and-thin advocate. What difficulty there was in retaining them ought to be faced. The question was not whether it was desirable to retain them, but whether it was possible. But it was possible, and any necessary disfigurement would be better than destroying them or removing them to a museum, which would be equally destroying them architecturally. They were, in fact, the only fourteenth-century work

remaining, and every step should be taken to preserve them. A rider should be added giving this direction to the architect.

Mr. Strachan Davidson appealed to Mr. Jackson to meet Professor Case's point, that the weight of the proposed double gables would tend to the ruin of the tower.

Mr. Child remarked that if Mr. Buckler's restorations had made the spire less beautiful than before, youthful attachments should not prevent something better being substituted. He still recalled the painfully dwarfing effect of Mr. Buckler's pinnacles when revealed by the removal of the scaffolding. As for a delegacy, it would be hard to get six bold men to face certain and general abuse.

Mr. Jackson said that, while he had been guided by the principle that not a stone should be tampered with of whatever remained of original design, where there was nothing to guide one, archæology would only hamper, and it was reasonable to aim at beauty. Now we could never know what was there before 1611, while to restore the design of 1611 would, he hoped, never be proposed, though to keep it would have been another question. As to the question between oblong and square piers, which was being fought by Professor Case, on the authority of Pugin he preferred Mr. Buckler's authority for oblong piers, since he had the advantage of scaffolding, and was bound for his own sake to take accurate measurements. Both sketch and measurements of Mr. Buckler he held in his hand, and now paid a tribute to the knowledge and taste of Mr. Buckler and the spirit in which he had approached the work. Of his own designs, the one he had laid aside as unsatisfactory he had incautiously shown to Mr. Bodley, who had preferred it. He himself rejected it because the pinnacles seemed to stand away from the spire and to dwarf it. In reply to Mr. Davidson, he might say there was no fear for the tower. Each group of pinnacles weighed about sixty tons, but the whole mass would almost stand without the spire. He might add that he had received a letter from Mr. Penrose eulogistic of the plan he himself preferred, and saying that Oxford had never been the same to him since the erection of Mr. Buckler's lofty pinnacles.

Professor Case disputed Mr. Jackson's estimate of the value of Pugin's observations. He was for a delegacy which need involve no delay, and which would give each design its fair chance. He dwelt upon the importance of the difference between oblong and square piers, and criticised adversely the design of Mr. Buckler and the compromise of Mr. Jackson. He challenged the latter to produce an example of a four-sided pinnacle, rising from eight gables upon a four-sided shaft.

Mr. Jackson observed that the overhanging of the shaft was found to be only $3\frac{1}{2}$ inches, which was a negligible quantity—that the design preferred by him saved on each cluster 10 tons of stone, and that the expense of it would be 530% less than the restoration of Mr. Buckler's design, and 300% less than his own alternative scheme.

Nine votes were given for the reproduction of Mr. Buckler's design; 11 for the design of 1611; 102 for Mr. Jackson's design preferred by himself, and 32 for his alternative design preferred by Mr. Bodley. On the third design being submitted as the substantive proposal, it was lost by 107 votes to 81, after which the proposal for a delegacy of six to be appointed by the vice-chancellors and proctors, in addition to themselves, to appoint an architect and select one of the present designs or a new one, was carried by 123 votes to 13.

TESSERÆ.

Mediæval Coffins.

STONE coffins were most common during the thirteenth century; they were, however, chiefly used for the interment of the upper classes, from the eleventh to the fourteenth century, after which they were generally, though gradually, superseded by coffins of lead, which latter are found to contain bodies embalmed, or preserved in cerecloths, much oftener than those of stone. The lids of the stone coffins were generally raised to the level of, or a few inches above, the pavement; and they are often found carved with crosses, or sculptured in high relief. The more ancient are angular, or ridge-shaped; and they form, indeed, the earliest specimens in this country of the monumental relics of the Middle Ages. Leaden coffins, though occasionally used earlier, as at the interment of Stephen, who died in 1154, and was buried in one at Faversham, in Kent, were not common till the fifteenth century, when the custom of embalming the body, preserving it in a liquid pickle, or covering it with cerecloth, became prevalent. The ancient leaden coffins were fitted to the shape of the body, and much resembled in form the outer case of an Egyptian mummy: they were often chested or enclosed in an outer coffin of wood, sometimes in one of stone, and have been frequently found to contain the liquid pickle in which the body was preserved. From the perishable quality of the materials, of which wooden coffins

were composed, little respecting their form or shape during the Middle Ages can be elucidated; it is, however, evident that the coffin lid was sometimes of an angular shape, *en dos d'âne*, as it is thus represented in an ancient illustration. In these it is probable that the bodies of the middle classes of society were buried, though even they were often interred without coffins. The bodies of the common people, down to so late an era as the sixteenth century, were only enveloped in a shroud, and so buried.

Egyptian and Assyrian Art.

The monuments of Egypt and Assyria signify two distinct conditions: they express that the Egyptian belonged to times of abstraction—his means of representation were emblematic, and his language conventional; the Assyrian belonged to times more prosaic, and dealt in modes more real. The art of the Egyptian was made almost entirely ministrant to his religious system; that of the Assyrian was more a record of his military triumphs. The personages of his sacred system caused the Egyptian an intentional departure from Nature in the more square—more simplified—more stern expression of human form as the medium of the spiritual idea; the Assyrian, more spherical in his forms, was more material—more realistic in treatments which aimed at a greater degree of anatomical truth, attention to details in accessorial particular, or excellence of execution. The Egyptian yearned after the Ideal—the Assyrian after the Picturesque. The Egyptian expressed Repose—the Assyrian, Action. In their painted monuments they, like the Egyptians, sought to express races and character as much by differences of flat colours or tints as by differences of form.

Fireproof Mortar.

Mortar for resisting the action of fire, and proper to be employed in building slight brick piers as substitutes for, or instead of employing, iron columns, may be made of pozzolano mixed with fresh-ground lime of chalk from the lower beds; and as real pozzolano is an imported substance and likely to be expensive, its place may be very well supplied by an artificial substance of similar character, produced by burning any marly clay that is fit for brick-making to a grey clinker, and reducing such clinker to a grain of the size of coarse sand. Three-fourths of this substance to one-fourth of fresh-ground lime, mixed dry in the first instance, and, when so mixed, rendered plastic by the addition of soft water, will yield a mortar capable of resisting fire for a long time, and water, if need be, as long as any bricks that can be set in it. The same mortar would be excellent, if time can be allowed for the setting as the work goes on, for ceilings, but care must be taken in using it for such purpose to guard against the consequences of its expansion in setting.

Thomas Telford.

A great revival in the study of the properties of elastic matter as regards strength took place about the year 1820, probably in consequence of the introduction of wrought-iron into the construction of suspension bridges, which has been attended with important results. Thomas Telford, though neither the contriver of suspension bridges, nor the introducer of them into Britain, deserves notice from the superior boldness and solidity of the Menai Bridge. Telford (and the same may be said of his contemporary Rennie) was more distinguished as a man of judgment, integrity and experience than as eminently original or philosophical. In this respect both yield to Smeaton, who, with Watt, was the founder (each in his own department) of modern engineering. But the beautiful and truly workmanlike structure of the Menai Bridge inaugurated the era of the extensive introduction of that admirable material, wrought-iron, into great permanent structures exposed to heavy strains. Cast-iron had been used much earlier, as in the bridge erected at Colebrookdale in 1777 by Mr. Derby, and in the very beautiful arch at Sunderland, which dates from 1796. The span of the Menai Bridge is 580 feet, the whole quantity of iron used was 2,186 tons, the transverse section of the suspending chains or bars was 260 square inches, supporting a strain of 1,094½ tons. This was a work quite unexampled at the time of its erection (1826), and showed a sagacious confidence in the employment of a material then comparatively little trusted. Telford never made extensive experiments on the resistance of solids. Some special ones were indeed made under his direction on wrought-iron in particular, but in general he seems to have relied upon the old ones of Musschenbroek and Buffon. The two persons who first in recent times vigorously applied themselves to the practical determination of the data of resistance so long deficient were Tredgold, a private engineer, and Professor Barlow, of Woolwich. The data they obtained have since been generally used, not only in this but in other countries. Tredgold's works (on "Carpentry," "Strength of Timber," &c.) show a very great aptitude in applying the results of science to practice, and an acquaintance with both which is rarely attained. Mr. Eaton Hodgkinson has made many valuable additions to Tredgold's work.

The Architect, June 9th 1893.

Printed by J. P. & C. 43, 54, 55, 56, 57, 58, 59, 60, 61, 62, 63, 64, 65, 66, 67, 68, 69, 70, 71, 72, 73, 74, 75, 76, 77, 78, 79, 80, 81, 82, 83, 84, 85, 86, 87, 88, 89, 90, 91, 92, 93, 94, 95, 96, 97, 98, 99, 100, 101, 102, 103, 104, 105, 106, 107, 108, 109, 110, 111, 112, 113, 114, 115, 116, 117, 118, 119, 120, 121, 122, 123, 124, 125, 126, 127, 128, 129, 130, 131, 132, 133, 134, 135, 136, 137, 138, 139, 140, 141, 142, 143, 144, 145, 146, 147, 148, 149, 150, 151, 152, 153, 154, 155, 156, 157, 158, 159, 160, 161, 162, 163, 164, 165, 166, 167, 168, 169, 170, 171, 172, 173, 174, 175, 176, 177, 178, 179, 180, 181, 182, 183, 184, 185, 186, 187, 188, 189, 190, 191, 192, 193, 194, 195, 196, 197, 198, 199, 200, 201, 202, 203, 204, 205, 206, 207, 208, 209, 210, 211, 212, 213, 214, 215, 216, 217, 218, 219, 220, 221, 222, 223, 224, 225, 226, 227, 228, 229, 230, 231, 232, 233, 234, 235, 236, 237, 238, 239, 240, 241, 242, 243, 244, 245, 246, 247, 248, 249, 250, 251, 252, 253, 254, 255, 256, 257, 258, 259, 260, 261, 262, 263, 264, 265, 266, 267, 268, 269, 270, 271, 272, 273, 274, 275, 276, 277, 278, 279, 280, 281, 282, 283, 284, 285, 286, 287, 288, 289, 290, 291, 292, 293, 294, 295, 296, 297, 298, 299, 300, 301, 302, 303, 304, 305, 306, 307, 308, 309, 310, 311, 312, 313, 314, 315, 316, 317, 318, 319, 320, 321, 322, 323, 324, 325, 326, 327, 328, 329, 330, 331, 332, 333, 334, 335, 336, 337, 338, 339, 340, 341, 342, 343, 344, 345, 346, 347, 348, 349, 350, 351, 352, 353, 354, 355, 356, 357, 358, 359, 360, 361, 362, 363, 364, 365, 366, 367, 368, 369, 370, 371, 372, 373, 374, 375, 376, 377, 378, 379, 380, 381, 382, 383, 384, 385, 386, 387, 388, 389, 390, 391, 392, 393, 394, 395, 396, 397, 398, 399, 400, 401, 402, 403, 404, 405, 406, 407, 408, 409, 410, 411, 412, 413, 414, 415, 416, 417, 418, 419, 420, 421, 422, 423, 424, 425, 426, 427, 428, 429, 430, 431, 432, 433, 434, 435, 436, 437, 438, 439, 440, 441, 442, 443, 444, 445, 446, 447, 448, 449, 450, 451, 452, 453, 454, 455, 456, 457, 458, 459, 460, 461, 462, 463, 464, 465, 466, 467, 468, 469, 470, 471, 472, 473, 474, 475, 476, 477, 478, 479, 480, 481, 482, 483, 484, 485, 486, 487, 488, 489, 490, 491, 492, 493, 494, 495, 496, 497, 498, 499, 500, 501, 502, 503, 504, 505, 506, 507, 508, 509, 510, 511, 512, 513, 514, 515, 516, 517, 518, 519, 520, 521, 522, 523, 524, 525, 526, 527, 528, 529, 530, 531, 532, 533, 534, 535, 536, 537, 538, 539, 540, 541, 542, 543, 544, 545, 546, 547, 548, 549, 550, 551, 552, 553, 554, 555, 556, 557, 558, 559, 560, 561, 562, 563, 564, 565, 566, 567, 568, 569, 570, 571, 572, 573, 574, 575, 576, 577, 578, 579, 580, 581, 582, 583, 584, 585, 586, 587, 588, 589, 590, 591, 592, 593, 594, 595, 596, 597, 598, 599, 600, 601, 602, 603, 604, 605, 606, 607, 608, 609, 610, 611, 612, 613, 614, 615, 616, 617, 618, 619, 620, 621, 622, 623, 624, 625, 626, 627, 628, 629, 630, 631, 632, 633, 634, 635, 636, 637, 638, 639, 640, 641, 642, 643, 644, 645, 646, 647, 648, 649, 650, 651, 652, 653, 654, 655, 656, 657, 658, 659, 660, 661, 662, 663, 664, 665, 666, 667, 668, 669, 670, 671, 672, 673, 674, 675, 676, 677, 678, 679, 680, 681, 682, 683, 684, 685, 686, 687, 688, 689, 690, 691, 692, 693, 694, 695, 696, 697, 698, 699, 700, 701, 702, 703, 704, 705, 706, 707, 708, 709, 710, 711, 712, 713, 714, 715, 716, 717, 718, 719, 720, 721, 722, 723, 724, 725, 726, 727, 728, 729, 730, 731, 732, 733, 734, 735, 736, 737, 738, 739, 740, 741, 742, 743, 744, 745, 746, 747, 748, 749, 750, 751, 752, 753, 754, 755, 756, 757, 758, 759, 760, 761, 762, 763, 764, 765, 766, 767, 768, 769, 770, 771, 772, 773, 774, 775, 776, 777, 778, 779, 780, 781, 782, 783, 784, 785, 786, 787, 788, 789, 790, 791, 792, 793, 794, 795, 796, 797, 798, 799, 800, 801, 802, 803, 804, 805, 806, 807, 808, 809, 810, 811, 812, 813, 814, 815, 816, 817, 818, 819, 820, 821, 822, 823, 824, 825, 826, 827, 828, 829, 830, 831, 832, 833, 834, 835, 836, 837, 838, 839, 840, 841, 842, 843, 844, 845, 846, 847, 848, 849, 850, 851, 852, 853, 854, 855, 856, 857, 858, 859, 860, 861, 862, 863, 864, 865, 866, 867, 868, 869, 870, 871, 872, 873, 874, 875, 876, 877, 878, 879, 880, 881, 882, 883, 884, 885, 886, 887, 888, 889, 890, 891, 892, 893, 894, 895, 896, 897, 898, 899, 900, 901, 902, 903, 904, 905, 906, 907, 908, 909, 910, 911, 912, 913, 914, 915, 916, 917, 918, 919, 920, 921, 922, 923, 924, 925, 926, 927, 928, 929, 930, 931, 932, 933, 934, 935, 936, 937, 938, 939, 940, 941, 942, 943, 944, 945, 946, 947, 948, 949, 950, 951, 952, 953, 954, 955, 956, 957, 958, 959, 960, 961, 962, 963, 964, 965, 966, 967, 968, 969, 970, 971, 972, 973, 974, 975, 976, 977, 978, 979, 980, 981, 982, 983, 984, 985, 986, 987, 988, 989, 990, 991, 992, 993, 994, 995, 996, 997, 998, 999, 1000.

CHRIST CHURCH, FENTON.
CHARLES LYNAM, F.S.A., Architect.

NEW PREMISES, SHOE LANE, E.C.

ILLUSTRATIONS.

CHRIST CHURCH, FENTON.

THE church consists of a nave of six bays, with clerestory and aisles, and north and south porches; a chancel, with a chapel on the south side, and a clergy vestry on the north; also a north transept, containing a choir vestry and an organ chamber. The foundations for a western tower have also been put in. The floor space of the church will accommodate about 1,000 worshippers. The chancel is enclosed by open oak screens, and fitted with oak stalls, whilst benches are provided for the church generally. The style is English Decorated, and was dictated by the requirement of the committee that certain prominent features of the former church should be re-used. In the gable of the north porch a niche has been provided in which a figure of "Our Lord in Glory" has been placed. The chancel is spacious, and the altar well raised. The side chapel has a separate altar, and is fitted with chairs for the daily services. Besides the north and south porches there are two exit doorways at the east end of the aisles. The heating vault is beneath the clergy vestry, and where the hot-water pipes are laid below the floor, openings are formed in the passages above the pipes of pierced terracotta. The chancel is lined with ashlar stone; all the other facings are of bricks both inside and outside, and in each case they are varied in colours not in patterns, but promiscuously, as furnished by the peculiarities of the bricks themselves. The roofs are open-timbered, unvarnished, with an external covering of lead to the aisles and slates elsewhere. The floors are laid with deal blocks and tiles in the passages and sanctuaries. The new church extends beyond the boundaries of the former one into the churchyard, and consequently the disturbance of former interments was necessary; and a churchyard cross of considerable dimensions has been erected commemorative of this unavoidable work. The total cost of the buildings and fittings was something under 7,000/. Mr. CHARLES LYNAM, F.S.A., Stoke-upon-Trent, is the architect.

NEW PREMISES, SHOE LANE, E.C.

THIS building, comprising an area of some 3,000 feet superficial, is being built in a very substantial manner for a printing warehouse. The fronts are of Portland stone (Whit bed), the whole of the front portions of basement being in white glazed bricks (Farnley Iron Company). The builders are Messrs. KIRBY & CHASE, of Hornsey Road, and the architect, Mr. HERBERT KNIGHT, Aldermanbury, E.C.

HOUSE, BROADSTAIRS.

THIS house will shortly be erected for Mr. F. KING-COCHRAM on a piece of land situate at Broadstairs, which adjoins the Coastguards' Station and Bleak House, the house in which CHARLES DICKENS wrote and took the name for his novel. The window of his favourite room overlooks the grounds, the rustic pier (mentioned in his book), the bay, &c. The front, shown in the illustration, will overlook the sea. The lower portion of the house will be built with bright red bricks, whilst all that portion above the level of the window sills will be in depeter work, with the gables half timbered, except the bay window and the quoins, which will also be in red bricks. The roofs will be covered with Broseley tiles. Mr. WILLIAM A. BURR, of 65 Chancery Lane, is the architect.

HYDRAULIC LIFTS.

WE announced last week that Mr. Robert Carey would read a paper on the above subject at the meeting of the Society of Engineers, held on Monday, the 5th inst.

Mr. Carey said that: Having been engaged for many years in the construction and working of lifts of various kinds, he proposed to place the results of his experience before the Society in the hope that the information conveyed might be of practical use to the members. Although he proposed dealing mainly with hydraulic lifts, he thought it desirable to introduce the subject by a brief reference to lifts of other kinds and of lighter character. He need hardly point out that there was an almost endless variety of hand-power lifts, and lifts which are actuated by belting from pulleys or shafting. The latter are generally constructed with worm and wheel gearing, there being three pulleys on the worm shaft, the centre one being half the

width of the others and keyed on to the shaft, the two outside pulleys running loose. There are two belts for driving, one open and the other crossed, and as the open or the crossed belt is brought on to the centre fast pulley, the lift is driven up or down. When the two belts are both clear of the centre pulley the lift is at rest. The balance weight should be considerably heavier than the empty cage, so as to divide the work. Some engineers object to worm and wheel gearing on account of the loss of power by friction, but the worm and wheel has the great advantage that it will not allow the loaded cage to run down. There should, however, be a small brake on the worm shaft applied automatically when the two belts are on the two loose pulleys, clear of the centre pulley. The office of the brake is to cause the lift to stop exactly at the same place, when the belts are struck off by the automatic stops at the top or bottom of the travel of the lift.

There is one form of power lift which has not had the extended use that might have been expected, considering it has been successfully working for many years. This is the continuous passenger lift, which is constructed with a number of cages attached to powerful steel pitched chains, at equal distances apart. They are kept continually moving, and hence the name, the cages always ascending on one side of the well-hole and descending on the other. They move at a slow rate of speed, so that the passengers may step in and out of the cages as they pass the various floors, and with a very little practice one can enter or leave with perfect ease. There is no waiting for this lift, as there is always a cage going up or coming down ready for the passenger to step into. No attendant is required, except to look after the driving engine. The continuous lift might be driven by an electric motor, and would make a good form of electric lift, the motor requiring very little attention.

The electric lift has recently been brought into notice in consequence of the facility with which this form of power can now be obtained, but almost of necessity they must have worm and wheel gearing, otherwise the motor has to be very large so as to run slowly, and the cost of the large motor is nearly prohibitory. There are other objections. It is very difficult to get the worm and wheel so truly cut that the cage moves perfectly smoothly, so that slight waves of motion are felt. Further, it is doubtful whether the electric lift can ever be quite as safe as the hydraulic lift, and safety is an absolute *sine qua non* in all lifts, particularly those for passengers. For these reasons the author is strongly of opinion that it will be long before electric power can compete successfully with the almost perfect application of hydraulic power for passenger use. Lifts are becoming more and more a necessity every day; they are not now regarded as luxuries, as they used to be not many years ago, but they have taken their place as a labour-saving appliance of great utility, and in a great many instances they are absolutely indispensable.

Of all lifts the most important is that used for passengers, and more attention has naturally been bestowed upon each detail connected with these lifts than upon the details of other kinds. The failure of any important part of a passenger lift may be attended by a serious accident involving loss of life, therefore great care has to be taken that all parts are of ample strength for the work demanded of them. This of course is so in all machine design, but where life is directly dependent upon it, special care must be exercised, and many parts may be duplicated simply with this object in view.

He ventured to say, without fear of contradiction, that at present no mode of actuating a lift surpasses, or in fact equals, that of water under-pressure. It may be open to discussion whether high pressure or low pressure is superior. High pressure, it is assumed, is obtained by pumping water into an accumulator loaded to give the desired pressure, and low pressure by gravity from a tank fixed at some altitude. Both systems have their peculiar advantages and disadvantages. The high pressure has the advantage that the machines actuated by it are comparatively small, which is a greater advantage than might appear at first sight. The pipes also are small, and can be run without attracting attention in positions and places where the large pipes necessary for the low pressure would be most unsightly and almost inadmissible, and where, as in most parts of business London, the high-pressure water can be obtained from the Hydraulic Power Company's mains at a very reasonable charge, the high pressure is far the best. But although there are a few other towns fortunate enough to possess the same facility, such as Liverpool, Birmingham, Hull, &c., yet there are many more which depend upon the low pressure from the ordinary street mains, or must produce the pressure for themselves by pumping either into an accumulator or into a tank, and the question has to be decided which is the best. If there is only one lift to be worked, then in most cases it is preferable to pump into a tank placed as high as possible. If many machines have to be driven, then an accumulator and high-pressure pumps are to be preferred. But each case must be considered and decided separately, sometimes one and sometimes the other system being best suited for the case; no

hard-and-fast rule can be laid down as to which is the best in all cases.

The advantages of the low-pressure system are quietness, and that when a tank is used for the water-supply it can be large enough to hold sufficient water for the lift to make several trips after the pumps have stopped working. The disadvantages are the large space occupied by the machinery and pipes and their unsightliness, also the extra cost due to their size. On the other hand, the cost of the high-pressure pumps and accumulator would often be more than that of the low-pressure pumps and tanks, including the larger pipes and machines. Both systems will work satisfactorily. In some cases the low-pressure tanks and pipes are fitted with fire hydrants, and afford a certain amount of protection against fire.

Some idea of the advantage of the Power Company's high-pressure water may be obtained by the following simple calculation:—Their charge is 20% for 100,000 gallons of water used in one quarter, the pressure is at least 700 lbs. per square inch, and the energy stored in the water amounts to about 1,610,000,000 foot pounds. 20% would pay for 600,000 gallons of town water at 9d. per 1,000 gallons, a fair average price, and assuming 50 lbs. pressure per square inch would represent about 690,000,000 foot pounds, there would therefore be a gain of 920,000,000 foot pounds by using the Power Company's water, or a saving of about 57 per cent.

There are very many kinds of hydraulic lifts, but there are two broad distinctions, viz. the direct-acting and the suspended. The direct-acting has the cage or car thrust up by a ram beneath it, while the suspended has the cage pulled up by ropes or chains from above, and it is impossible to say which system is the better. For low travels no doubt the direct-acting is generally the better, but for very high lifts it is questionable whether the suspended lift is not the safer as well as the better for other reasons, paradoxical as it may sound. There is little doubt but that the suspended lift is safer than the direct-acting lift, having the weight of the ram and cage counterbalanced by ropes or chains attached to the cage, and passed over sheaves at the top of the shaft and down to the balance weights. The cage and ropes, as well as the over-head sheaves, are subjected to much greater stress and strain in this form than in the suspended lift, because of the great weight of the ram which has to be balanced as well as the cage, the weight of the cage only having to be balanced in the suspended lift.

For moderate heights of travel there is no safer or better hydraulic lift than that known as the hydraulic balanced direct-acting lift. In this lift the weight of the cage and ram are balanced by a separate machine, called the balancing cylinder. The water actuating the lift never enters the lift cylinder at all, but acts on the actuating ram of the balancing cylinder only. There are several kinds of balancing cylinders, but they all practically consist of a displacement or balance ram, the displacement of which is equal to the displacement of the lift ram. Weights are added to the displacement ram until the pressure created is such that the weight of the empty cage and lift ram will just descend, overcoming friction and raising the displacement ram with its weights. The water contained in the lift cylinder and balancing cylinder oscillates between the two cylinders; when the lift is up it is in the lift cylinder, when the lift is down it is in the balancing cylinder, means being provided for making up any loss of water through the stuffing boxes. The water, in fact, performs the part of the beam in a pair of scales; the actuating water, when admitted through the controlling valve, acts on the actuating ram, exerting a thrust on the displacement ram, increasing the pressure beneath it to the necessary extent to raise the weight of the lift ram, cage, and live load.

The object of the balancing cylinder is to obviate the use of the balance weight attached to the cage by chains or ropes, to get rid of the overhead sheaves, and to reduce the quantity of water used to the smallest practicable amount. In the case of direct-acting lifts working from the Hydraulic Power Company's mains, the one great advantage is the reduction of water used, as the pressure of 700 lbs. on the square inch would in almost all cases be more than enough to raise the weight of the ram and cage with the maximum live load without any mode of balancing whatever, but a lift without balance (as the ram must be large enough in diameter to give strength as a column) if worked much would use such large quantities of water that the cost of working would be almost prohibitive. For instance, if we take a lift of 50 feet travel to raise a load of say five persons and attendant, or about 9 cwt., making 200 trips per day, the ram for this height must not be less than $3\frac{1}{2}$ inch diameter, and would use about twenty-one gallons per trip, which would make 4,200 per day, or 327,600 gallons per quarter, and would cost, according to the Power Company's charges, somewhere about 45%. If, however, the same lift be provided with a balancing cylinder, it would only use eight gallons per trip, or 1,600 gallons per day, or 124,800 gallons per quarter, and the Power Company's charge would be 22% 16s., showing an annual saving of about 88% 16s. by the use of the balancing cylinder; it is therefore well worth the

extra first outlay. But even with the balancing cylinder, as now constructed, the same amount of water is used to raise a light load as a heavy one, the maximum amount of water is always used, although the minimum load may be raised. To construct the balancing cylinder and other parts so that a proportionate amount of water should be used according to the weight raised, is perhaps the only direction in which the direct-acting hydraulic balanced lift can be much improved. Great expense is sometimes incurred in order to balance what is called "the loss by protrusion," that is to equalise the lifting power throughout the entire travel, for unless some means are provided for this, the direct-acting lift will start with a much heavier load than it will carry to the top of its travel, for as the lift ram protrudes farther and farther out of the cylinder, the pressure of water acting on its bottom end diminishes according to the depth. In other words, it loses power exactly in proportion to the weight of water necessary to fill the space before occupied by the ram, therefore if the ram displaces 50 gallons of water, it would lose about 500 lbs. of its lifting power in ascending to the top of its stroke, and must be designed to start with this extra power, hence the loss. In the old form of direct-acting lift, with balance weights attached to the cage by chains passing over top sheaves, the weight of the chains is made to perform this office and equalise the power throughout the whole travel. But where the balancing cylinder is used, some other method must be adopted if the protrusion is balanced at all. In very high lifts it is almost a necessity on account of the great loss of power there would otherwise be, and the extra amount of water that would be used. This does not, however, apply to low-pressure balanced lifts in the same degree as to high-pressure ones, because in the low-pressure lifts the weight of water necessary to actuate the lift may be made to nearly or quite neutralise the loss by protrusion. But this cannot be done with the high-pressure lift, and therefore other devices have to be resorted to, such as enormously heavy chains made of cast-iron blocks for links attached to the moving cross-head of the balancing ram or immensely heavy levers or moving weights so constructed as to gradually increase the weight pressing on the balancing or displacement ram, thus increasing the pressure in the lift cylinder, as the end of the lift ram rises higher and higher, keeping the same pressure always on the bottom end of the ram, no matter in what part of the cylinder it may be. Some of these arrangements for balancing the protrusions are very costly and occupy a large space, the only justification for the extra complication and expense being the extra saving of actuating water, but this generally amply repays the outlay. The economising of water is a very important consideration, as it is a continual saving in the cost of working. This point will be more closely examined later on, when a system in which a proportionate amount of water used according to the load lifted is described.

Direct-acting lifts without any overhead sheaves or ropes, but balanced from below, patented and made by the author of the paper, are suitable only for low pressures. They are quite as safe as the direct-acting lifts with separate balancing cylinder, the power is constant throughout the stroke, and no space is required other than that necessary for the lift itself. The construction is simple, and comparatively cheap. The cylinder is made of the diameter or area necessary to give the lifting power calculated as the diameter of the ram in the ordinary old form of direct-acting lift. It is, therefore, smaller by the clearance round the ram than the old form, but it is bored the whole length. The ram is made of steel as small as strength will permit, and a piston is attached to its bottom end, the cage being secured to the top. The weight of the ram and cage is balanced by a weight working up and down close to the cylinder in the well, and attached to the piston in the lift cylinder by means of chains or wire ropes passing over sheaves fixed to the top of the cylinder. The pressure water, after passing the starting valve, is taken to the bottom of the cylinder in the well by a pipe, and the exhaust is taken from the starting valve into the top of the lift cylinder, there being a large exhaust pipe from the top of the cylinder to the drain. It will be seen that the water is always in the cylinder; as the piston rises the pressure above diminishes, and as it descends the pressure above increases, thus equalising the power throughout the entire travel. The protrusion of the small ram is compensated for by the weight of the chains or ropes to balance weight. This form of lift has been found to be very successful for moderate heights, and is eminently suited for very low pressures of water, or where a very heavy load is required to be raised by a low pressure of water.

Suspended lifts, on account of their greater cheapness and their not requiring a well and cylinder sunk in the earth, are becoming more common than they were a few years ago. They have also been greatly improved in detail and construction. Chains have given place to wire ropes, the multiplying sheaves have been greatly increased in diameter with beneficial results, friction being reduced and the life of the wire ropes increased. For passenger use it is almost the universal practice now to suspend the cage by four wire ropes; for warehouse and goods

lifts sometimes purchasers are content with two, but very rarely one, except for very light loads. When there are four ropes each one is of ample strength to do the work alone, and they are carefully examined at frequent intervals, say once every month, to see if there are any signs of wear, and directly such are detected the rope is removed and a new one put in its place. It is very difficult to imagine that there is much danger from the failure of the ropes, especially if there is a good safety apparatus. It has been suggested that where there is more than one rope to carry the cage, all the weight should be carried by one and the other, or others should simply run idle, merely being kept taut by springs so that no stress or shocks can be communicated to them. By this arrangement it is claimed that the working rope alone will be liable to break; the others having to bear no strains will last much longer and be in a perfectly good condition long after the working rope is worn out. Should the working rope break, the other ropes being comparatively unworn will not be likely to break when the full weight of the cage is suddenly thrown upon them. He had no experience nor knowledge whether the ropes passing over the sheaves without being loaded would last much longer than the rope which had all the weight of the cage suspended thereon, but the probability is that they would. If so, perhaps this alone would be the most effectual safety arrangement that could be applied, as it could not fail to act when the critical moment arrived. Another suggestion is that, in the event of the working rope breaking, the other rope or ropes may be made to exert all their strength to apply the safety cams. It would thus be almost impossible for the cage to drop, or, in fact, descend at all until the ropes were again made right, for, assuming the ropes were so much worn that they were unable to withstand the shock of the weight of the cage being thrown on them, they would still be amply strong enough to pull the cams into action. This they must do before they take any strain at all worth mentioning, and therefore, before any shock could affect them, they would only have to compress the springs that in the ordinary course of working kept them just taut, slightly more than before the working rope broke. That would be all the extra work required of them, for when once the cams were in contact with the wooden slides or runners they would grip and hold fast should the cage be descending, but if ascending they would only drag on the runners but not bite. In the foregoing suggestions the principle is adopted that it is better to wear out one rope first, the others being kept in reserve to meet the contingency of the first rope breaking; if only one out of two or more breaks no great harm is done.

There are many kinds of safety appliances in use for preventing the descent of the cage should the suspending ropes break, and it appears to be the fashion, so to speak, to have for passenger-lifts four steel wire ropes, all doing equal duty, the safety apparatus being so constructed that, should any one of the four ropes break, the others pull into action the safety cams or grips. In most of these arrangements, however, there is the fault that if all four ropes were to break simultaneously the safety gear would not come into action at all; and in some, if two ropes were to break at the same instant, the other two would not apply the safety cams at all. To meet this contingency, a fifth rope of less strength than the other four is provided with the sole object of forcing the cams or grippers into action should all the other ropes break. The multiplication of ropes and the excellent safety appliances now in use leave little to be desired in preventing accidents by the failure of ropes, but there is another inherent source of danger connected with suspended lifts, although happily a remote one, that is the failure of the overhead sheaves or spindles. Beyond making these of extra strength, it is not usual to take any special precaution, the only protection that could be suggested would be a strong floor or grid under the top sheaves, but this would be inadmissible in most cases on account of its unsightliness and the obstruction of light. If, however, proper care be exercised in designing these parts, and testing them before they are erected, very little danger need be anticipated from this quarter.

Whilst considering the question of safety, he drew attention to the construction of entrance doors or gates, for, although not actually part of the lift, they are so nearly allied with it that their consideration should not be parted from it. There are endless patents and proposals bearing on this one point, and in the great majority the idea seems to be that the doors or gates should open automatically when the cage approaches the level of the floor, and close automatically when it passes away. This may be done with advantage at the top and bottom floors only, because when the case is approaching either of these floors the intention is to stop there, but with the intermediate doors it is different. The cage may be going past the floor, when it is worse than useless to open and close the door as it passes. The intermediate doors should be opened by hand, and closed automatically when the cage passes away from the floor. Bolts can be so arranged that the doors can only be opened when the cage is level with the floor. Another good arrangement is to lock the starting rope when the door is opened, the lift cannot then be started until the door is closed. In this case, of course,

the door does not close automatically, but has to be closed by hand before the cage can be moved.

All passenger lifts should be examined and a certificate given by a Government expert or inspector before they are allowed to be used for passenger traffic. Many lifts carry as many passengers during the day as a small line of railway in a country district, and, although the journey is short, if the lift is defective, the danger may be great. The time occupied by the inspection would also be short, and tests might be made in the presence of the inspector, who should have power to withhold his certificate unless he considers the lift perfectly safe. This would ensure that passenger lifts, at least, should be well designed and constructed, up to a certain standard of excellence. The inspection of warehouse lifts, where persons are allowed to travel in them, would soon follow, and the makers of these lifts would so be compelled to turn out good work. Extreme cheapness should not be the first consideration for machines of this kind when absolute safety is of the utmost importance. True economy is not always the same thing as small outlay, a thoroughly good machine is generally cheapest in the long run, although it may cost more in the first instance.

(To be continued.)

LOUTH ANTIQUARIAN SOCIETY.

AN excursion was recently made by this Society to interesting localities on the Wolds. Little Cawthorpe Manor House was visited among other places.

The Manor House was a residence of the Mottram family, and bears a date 1673. It is cruciform with four gables, having brick arches in the walls for the purposes of strengthening them. In one gable is a quartered shield, and in another a stove with the initials I. M. 60. The initials are doubtless that of some member of the Mottram family, one of whom had a seal with a death's head and the motto "Memento mori." A leaden water cistern of circular form, made of plates soldered together, ornamented with scroll work, and bearing the date 1710 was an object of interest.

Haugham wood was said to be part of the primeval British forest through which our painted ancestors ran in savage freedom. Of Muckton (Machetone) Domesday Book says, "There is a church and there are seven acres of meadow. There is underwood one mile long and four furlongs broad."

The rector pointed out the objects of interest. The church is dedicated to the Holy Trinity, and was restored in Salmonby stone some years ago by the late Mr. Fowler, who preserved the Norman arch between the nave and chancel. This arch affords a good example of zigzag moulding. The font belongs to the fifteenth century, and shows marks of the staple and hinge used to secure the cover, as required by an edict of the thirteenth century to prevent sacrilege. An ancient oak door with iron boss is preserved. A tombstone on the floor has the words "Elizabeth, wife of Richard Pickles, Rector of this parish." In the churchyard there is a tracery of the beautiful reticulated window taken from the western wall of the old church, and possibly due to the thirteenth century.

At Belleau (Elgelo) are the remains of buildings called "The Abbey," but which doubtless formed the abode of some noble family. The histories say it was a seat of the Earls of Lindsey, but some old documents speak of Hellowe (Belleau) as belonging to the Wells family. The buildings were surrounded by a moat, traces of which can still be seen. On the north there is an octagonal building used as a pigeon cote, but which was probably used as a garrison house. On the west the famous Belleau springs, from which the name is said to arise, come bubbling from under the wold escarpment and flow away in great volume to "join the brimming river," the Eau. Two archways, groined and ribbed with stone, together with an octagonal brick turret, still remain. The arches, having a double curvature and intersecting mouldings, were relegated to the fifteenth century. The stone used was oolitic and probably Lincoln. In the tower the stair is still *in situ*, the roof is of panelled brickwork, and there is a loophole looking to the north. At the apex of one of the arches and looking into the courtyard, there is a gigantic grotesque face with hairy arms, and one hand grasping something resembling a flower; the other hand is broken. This is locally known as the "Samson Stone," from the long hair of the figure, and doubtless it served as a base for a window above it. In the Willoughby Chapel at Spilsby there is a hairy man, and possibly there is some connection between the two.

The ancient hall used by the servants now serves as a barn, and has the stone tracery of handsome windows now bricked up, but which had glass inserted when the bishop visited Belleau. On the front of the dwelling-house is a vertical sundial of the Georgian period. The springs flow through the garden, and a multitude of trout, large and small, were seen in the transparent water darting hither and thither or hanging suspended motionless. An octagonal baptismal font with most beautiful tracery in the panels, and altogether of very superior

workmanship, was in the garden. This font is said to have belonged to Aby Church, which Cromwell is credited with destroying.

Belleau Church, dedicated to St. John the Baptist, occupies a site on an eminence overlooking the valley. The rector pointed out the various objects of interest. The arcade in the nave is early fourteenth-century work. In the chancel there is the figure of a crusader with a lion at his feet and his legs crossed above the knee, indicating that he had twice visited Palestine. His head is supported by angels, his visor is up, he looks as if the enemy was in view, and his sword is partially drawn. This figure is said to have been brought from Greenfield, and is possibly that of Endo de Greenesby, who founded Greenfield Convent in 1153. In the chancel is an Easter sepulchre and a piscina. In the graveyard there is the base and part of the shaft of a churchyard cross; over the late clerk there is a twelfth-century body stone, which formerly lay in front of the church.

Belleau is associated with Sir Henry Vane, the most able man of the Commonwealth, not even excepting "ye arch rebel" Cromwell himself. Saunders says:—"After the termination of the Civil War this place was sequestered to that eccentric character Sir Henry Vane, who amused himself here on Sundays in assembling and preaching to his country neighbours." Would that the present hour might lend another eccentric "character" of the kind!

In 1636 or 1637 Sir Henry Vane married Frances, the daughter of Sir Christopher Wray, of Ashby-cum-Fenby, and perhaps this may account for Vane living at Belleau.

The next place visited was Haugh, where Mr. Crow read an account of Sir John Bolle, who is buried in the chancel of Haugh Church.

Near Louth, in Lincolnshire, stands Thorpe Hall, an old mansion charmingly situated amongst delightful scenery, and connected with which is an old legend but comparatively little known. The elder branch of the ancient family of Bolle, or Bolles, settled here at an early period, and it is to Sir John Bolle, who lived in the reigns of Elizabeth and James I., that the legend more particularly relates. Sir John was celebrated as well for the gallantry with which he signalled himself as an officer in the army, in the memorable expedition against Cadiz in 1596, as for his activity, bravery and good conduct in Ireland. He commanded at the taking of the castles of Donolong and Lifford, during the administration of the Earl of Essex, by whom he was appointed governor of Kinsale. Queen Elizabeth conferred upon him the honour of knighthood after his return from Cadiz, and it is in connection with this gallant knight and his exploits at this place that the legend of "The Green Lady" has its origin.

Tradition assures us that, amongst the prisoners taken at Cadiz, it fell to the lot of Sir John Bolle to take charge of a lady of extraordinary beauty and of distinguished family and great wealth. This lady the noble knight treated with the care and tenderness which was the right of her sex, by endeavouring to soften and alleviate the heavy weary hours of her captivity. This generous care naturally evoked feelings of gratitude, and these ultimately warmed into love. This resulted in her throwing at the feet of the warrior her riches and her person, and such was her ardent passion that, when released, she entreated him to permit her to accompany him to England as his page. But the gallant knight had a wife at home, and neither the charms of the beautiful Spaniard, nor the powerful influence of her gold, could prevail. Like a true knight, therefore, he returned whither duty and honour alike called him, and the beautiful and inconsolable lady retired to a nunnery, there to spend the remainder of her days in sorrow and seclusion.

On Sir John Bolle's departure from Cadiz, the devoted Spaniard sent, as presents to his wife, a profusion of jewels and other valuables, amongst which was her portrait, taken as she was, dressed in green; a beautiful tapestry bed, wrought in gold by her own hands; and several casks full of plate, money and other treasure. Some of these articles, it is said, were, at the commencement of the present century, still in possession of the family; but the portrait was unfortunately lost, or disposed of in some way, half a century before. The picture being thus in green led to her being called in the neighbourhood of Thorpe Hall "The Green Lady." Tradition further records the superstitious belief that the old hall was haunted by her, and that she used nightly to take her seat in a particular tree near the mansion. It was also said that, during the lifetime of his son, Sir Charles Bolle, a knife and fork were always laid for her at table, if she choose to make her appearance.

The compiler of this account, who was then resident in Louth, well remembers the belief in many superstitious minds, some thirty-five years ago, that "The Green Lady" was occasionally to be seen walking about the grounds at midnight!

But to continue with our story. It seems that the attachment of the beautiful Spaniard to Sir John was such that it became the subject of a ballad, which was subsequently published in Percy's "Reliques of Ancient English Poetry."

Shenstone has also an elegant poem on the same subject, entitled "Love and Honour," concluding with the lines:—

And to the cloister's pensive scene
Elvira shaped her solitary way.

Sir John died in 1606, in the forty-sixth year of his age, and was interred in the chancel of Haugh Church, where a monument was erected to him, with a Latin inscription, bespeaking his accomplishments as a scholar and a soldier. His portrait, taken in 1596, when thirty-six years of age, having on the "chain of gold" spoken of in the poem, and a curious thumb-ring, set in massive gold, with the arms of the family, bearing sixteen quarterings, elegantly engraven and emblazoned, came into the possession of the Birch family, descendants of the Bolles. Captain T. Birch, of the 1st Life Guards, lived at Thorpe Hall about 1808.—Abridged from Chambers's "Book of Days."

The thumb-ring of Sir John Bolle was exhibited at an archaeological meeting held at Louth some years ago.

A clergyman of Thoresby used to offer a quaint prayer for rain "on Aby, Swaby, our town of Thoresby and the little village of Haugh, and my four-acre close in Saltfleetby, and if thou, Lord, dost not know it, there is a little bit of furze bush in the gateway." Mr. Cresswell made reference to a Mr. Bourne who in 1811 resided in Haugh Manor House, and who formed one of Princess Charlotte's escort to England. The house was built in the early part of the reign of Henry VII., and has a range of battlements along the front. The walls are of great thickness, the external casing being brick, and the interior perhaps of rubble. It still retains the great beams crossing the roof. One member was disappointed to find that it was not haunted, but was consoled by the information that there was a subterranean passage to Greenfield Priory, the entrance archway in the cellar being bricked up; but it was said the Greenfield end had been partially explored. Haugh at one time belonged to a family of the name of Hagh, but thereafter passed to the Bolles, there being an inscription in Boston Church to the memory of Richard Bolle, Esq., of Hagh, who died in 1519. In the floor of Haugh Church there are inscriptions to Joanna de Welby and Agnes de Clour, the first and second wives of John de Hagh, without dates; Isabella, wife of Richard de Hagh, dated 1417; John de Hagh, dated 1458; Thomas de Hagh, dated 14—; and Robert de Wyncceby 1425. In the south wall of the chancel is a slab surrounded by several shields fully charged and surmounted by a boar rampant, naissant pierced by a broken spear, and having the legend, "nec temere nec timide" (neither rashly nor timidly), which was the motto of the Thorpe Hall branch of the Bolle family. It is in memory of Charles Bolle, of Haugh, who died on February 8, 1590, and his four wives, Katherina Dimock de Skrivelsby, Brigitta Fane de Badsill in the county of Kent, Maria Powtrelle de West Hallam in the county of Derby, and Anna Dimock de Friskney. It further goes on to say that he was the father by Brigitta of John Bolle of Thorpe Hall, Knight, and Katherina the wife of Edward Carre, and by Maria of Elizabetha the spouse of Thomas Gilby.

On the north side of the chancel is the monument of Sir John Bolle. The knight is kneeling, and clad in armour; behind him are his three sons kneeling with clasped hands, clad in short cloaks with high collars and little shoulder capes, and each wearing a sword. Facing the knight is his lady kneeling with clasped hands, and behind her four daughters also kneeling. The lady has a closely-fitting cap, which permits her fine curls to be seen in front and behind. It has a tail hanging down to the waist. Round her neck there is a large ruff, and under that a collar; the sleeve of her dress, somewhat full at the shoulders, is marked with scroll pattern, and has a button at the wrist. The daughters are all clad alike, having close-fitting caps, slightly peaked in front, with ornaments round the external border. Each has a neck ruff and short shoulder cape and girdle. The figures are well executed and are nearly in full relief. The inscription names his wife and children, says he was distinguished for various erudition and military glory, that he was made a knight for his bravery in Spain, that he founded the colony at Loch Foyle, in Ireland, and that he took the castles of Donolong and Lifford, that he merited well of his country, and died on November 3, 1606. The church walls are of chalk, and are rapidly crumbling; there is a leper's squint or anchorite's hole, two corbels to carry the rood beam, and a twelfth-century arch. In the garden there is the panel of a tomb in Sicilian marble; it bears a shield, but the markings are obliterated. North of the church there is a row of about twenty venerable yew trees; it is said the number used to be seventy. There can be no doubt that Haugh was the seat of a monastery.

At an inquisition taken at Lincoln 22nd Edward III. to inquire into the value of the Manor and Church of Haugh, it was proved by the oath of Walter de Hildyok de Foston, Wm. Sampson de Bennington and others, that the monks of Haugh held one capital messuage, with a dove-cote worth per annum 30s. 4d., one water-mill worth 3cs. 4d. per annum, and 20 acres.

of meadow worth 30s. per annum. "Et sunt ibi spine crescentes in Lonedon pro focali, et valent per annum viginti solidos," i.e. there are thorns growing there in the Lonedon, for fuel, worth 20s. per annum. The monks of Hagh had a yearly rent from possessions in Grantham of 2s. 4d., and in Lincoln the same amount. One hundred and twenty-three and one-third acres lie "warrett" are valued at nothing because they lie in common. The rents of the inhabitants (nativorum) are 6s. 10d. The Church of Haugh was taxed in former times at 26l. 3s. 4d., is not at this day worth 20l., and the aforesaid jurors, being asked if the prior of Hagh or his predecessors possessed any other land or tenements besides the said manor, church, and possessions, answered that they had none. There was one windmill broken a long time since, and not able to be repaired. At the Conquest Haugh was given to the Bishop of Durham.

An interesting relic of the Bolle family was exhibited; it bore a ticket with the following inscription:—

"This hinge is from the door of Alton Church Porch (Hampshire) in which Colonel John Bolles fell (1643) whilst defending it and his followers from an attack made upon them by the Parliamentary forces. The door shews the marks of the bullets fired at the time."

NORTHERN ARCHITECTURAL ASSOCIATION.

ON Saturday the members of this Architectural Association, whose headquarters are in Newcastle, had their first summer excursion to the Hartlepoons. The Association, which was instituted in 1858, now has a membership of 100. Among the party were Mr. J. H. Morton, president, Mr. Joseph Oswald, vice-president, Mr. J. T. Cackett, hon. treasurer, and Mr. Arthur B. Plummer, hon. secretary. Leaving Newcastle the party arrived at Hartlepool at 2.23 in the afternoon. The first visit was to the fine old church of St. Hilda's, where they were kindly conducted by Mr. Carse, under whose direction the work of restoring the grand old tower is proceeding. A walk was then taken by way of the ferry through the docks at West Hartlepool, and thence to the Municipal Buildings in Upper Church Street. The tour wound up with visits to the churches of St. Paul, St. Aidan, and All Saints', Stranton, Mr. Morton, president of the Association, being the architect of St. Aidan's, and the renovator of Stranton's ancient edifice. Although the weather was somewhat showery, a most enjoyable afternoon was spent. The company afterwards dined at the Royal Hotel, West Hartlepool, and took the nine o'clock train home. It is intended to hold more meetings in neighbouring towns during the present year than has been the case heretofore, it being felt that the interest in the Association should be of a more general character. The members visit Durham on July 1, and Sunderland on July 29, whilst the annual excursion is to York, on the 12th prox.

NORTH STAFFORDSHIRE FIELD CLUB.

THE second excursion of the season in connection with the North Staffordshire Naturalists' Field Club and Archaeological Society has just taken place, a report of which is given in the *Staffordshire Advertiser*. The weather was fine and warm, and as the excursion was through some of the loveliest scenery in North Staffordshire, it was scarcely surprising that a larger number than usual turned up. The party travelled from Stoke to Uttoxeter, where they were joined by the leader, Mr. T. S. Wilkins, and thence on to Rocester and to Barrow Hill, the residence of Captain Dawson. A visit was first paid to the site of a Roman camp on the estate, the well which supplied the camp being pointed out on the way through the grounds. The camp itself is admirably placed, commanding a splendid view of the surrounding country, and is an excellent example of its kind. It is also interesting from the fact that numerous Roman coins and pieces of broken Roman pottery have been found close to, and are still sometimes recovered.

Mr. Charles Lynam has given the following notes on Barrow Hill and Wootton Lodge:—Barrow Hill is situated about three-quarters of a mile north of Rocester; the River Churnet flows to its west, Denstone being on the opposite side of the valley. Close to the house now called Barrow Hill are the remains of a camp of Roman origin. The first point which strikes the visitor to this camp is its remarkable contrast to other well-known camps in this county, that at Alton, now called Bunbury Wood, being the nearest, but unknown to the many visitors to Alton Towers. Bunbury Wood is a fair example of the camps not Roman; irregular in shape, following for a large part of its boundary the varying edge of the summit of a deep and steep declivity, surrounded by one or more fosses with their accompanying ramparts, and inclosing a considerable area, from which command is had towards the neighbouring district. Of this class of camp there are many within this county, but this is not the case with those of Roman type, as at Barrow Hill, which is simply rectangular, fairly level on its surface, and had its

straight cross roads from side to side—evinced its use as a soldier's camp, contrasting with those of British or Saxon origin which afforded a refuge for the people of a whole district and their cattle in the time of danger or attack. Roman camps were usually situated on or between or near to their main or bye roads, and a roadway is traceable along the eastern side of this camp at Barrow Hill. This camp and that at Chesterton—the latter being much the larger—bear a strong resemblance to one another in their situation and construction. Rocester is undoubtedly a name of Roman origin, and the same may also be said of Uttoxeter. These two places, not far apart, may be regarded as a centre of Roman remains not even yet fully described or explored. Wootton Lodge is a mansion which for its romantic situation, picturesque effect, and architectural excellence may be said to be unrivalled in this county. It is wholly built of wrought stone, its proportions are magnificent, and as an example of the English Renaissance it is most admirable. The county histories barely mention it, and relate but very little indeed of its owners or builders. So here is an open field for the student of the architectural revival in England and of county history.

POST OFFICE, WASHINGTON.

THE building of which we give an engraving is to be erected for the accommodation of the Washington City Post Office, Mr. W. J. Edbrooke, supervising architect, Treasury Department, which will occupy the first floor and all that part of the basement not required for heating-apparatus or elevator and electric-light plant. It is also likely that a large part or perhaps the whole of the second storey will be required for offices connected with the City Post Office, and in the topmost storey sitting-room, dormitory and other accommodations will be provided for the use of railway postal clerks.

The Act of Congress authorising the erection of the building provided that it should be eight storeys in height, but no assignment has yet been made of the large number of office-rooms which will be available in the upper storeys. The building will occupy the entire block (Square 323) bounded by Pennsylvania Avenue and D Street on the north, by 11th Street on the east, by 12th Street on the west, and by C Street on the south. The main front on Pennsylvania Avenue will be 200 feet in length, and the depth of the building to C Street will be about 300 feet. The elevators and staircases for access to the upper storeys will be near the entrances on 11th and 12th Street fronts. The main post-office entrance is on the Pennsylvania Avenue front, and the entrance on C Street will be used entirely by the City Post Office for the receipt and despatch of mail. The height of the tower from the sidewalk to the finial is about 300 feet; the clock-faces, 20 feet in diameter, are about 250 feet above the pavement. The width of the tower is 40 feet and it will be visible from the Capitol along the entire length of Pennsylvania Avenue, and from the greater portion of the various sections of the city. The material used for the exterior will probably be granite. Over the entrance arches of the main front, a projecting balcony, over each, above the second storey, will form supporting pedestals for groups of statuary emblematic of the postal service, the coat-of-arms of the United States, &c. The spandrels of the arches at all the entrances will be enriched with carved ornaments, but there will be but little other carved-work on the exterior of the building. The general plan of the building is that of a series of offices around an interior court. The entire central portion above the second storey will be an open light-well about 100 by 200 feet in dimensions, roofed over with ornamental iron trusses, and covered with glass skylight, around which will be a clear storey of moderate height furnished with movable sash. At the level of each storey the corridors, extending around the entire court and affording access to the various offices, will be floored with glass. These corridors are supported by a colonnade and relieved by ornamental wrought-iron work. The main body of the post-office working-room is immediately under this light-well, and will be protected by a curved glass ceiling, supported by elliptical ornamental trusses which spring from columns independent of those that support the galleries. The spring of these trusses will be at a level somewhat below the first-storey ceiling, which admits of a series of openings above the post-office screen, which will give direct light and ventilation to the public lobby of the first storey. The corridor partitions of all the first floor offices will be of glass, and as glass is used, as before stated, for the ceiling, it is believed that this lobby will be well lighted.

The following are the main features of the arrangement of the post office floor:—On the east of the front entrance will be the public and private offices of the postmaster and assistant postmaster, with necessary toilet-rooms, vaults, &c. Between these offices and the 11th Street or east entrance will be three elevators and a commodious staircase. Beyond the entrance is placed the cashier's office and other subordinate departments. On the west of the principal entrance, extending on 12th Street to the staircase and elevators on that side of

the building, is located the money-order office, with vaults, toilet-rooms, &c. Beyond the 12th Street entrance is placed the registry division with its public lobby. South of the registry division are vaults, toilet-rooms, &c., and the southwest corner of the building is occupied by the apartment for accommodation of mail for both Houses of Congress. The

main lobby between the offices heretofore enumerated and the main post-office working-room is 15 feet in width. The working-room of the office has an area of over 34,000 square feet. Each floor above the first storey will have about 20,000 square feet of actual office space, exclusive of corridors, vaults, toilet-rooms, &c.

EDINBURGH ARCHITECTURAL ASSOCIATION.

THE annual excursion of the Edinburgh Architectural Association took place to Cupar and district on Saturday. The members of the Association travelled to Cupar by train, and upon arriving walked to the parish church, where they were received by the Rev. John Scoular. Of the church built in connection with the Priory of St. Andrews in 1415 only a fragment remains. In 1620 the tower was heightened and capped with a lofty spire, which, being off the square, has from one point of view a somewhat curious effect. Inside the church there is a finely-preserved fifteenth-century effigy of Sir John Fernie in armour. Several interesting ancient monuments in the burying-ground were examined. One of these marks the resting-place of the heads of two and the hands of another who suffered martyrdom at Edinburgh about the end of the eighteenth century. Proceeding next to Preston Lodge, the party were received by Mr. John Jamieson, who allowed them full access to his mansion and pleasure grounds. Preston Lodge is a charming piece of seventeenth century work, with a curious blending of classic and Gothic details. The staircase, which in the history of the domestic architecture of Scotland is a matter of considerable importance, is the grand feature of the house. Although only 15 feet by 11 feet 6 inches, it has a quaint and dignified appearance unsurpassed by anything in Scotland at that age. The front rooms contain charming retreats not unlike what are regarded elsewhere as oratories, and over an interesting fireplace there is a pretty panel picture on canvas. As in the case of many of the houses in old Edinburgh, the picture at one time had been hidden beneath a coat of paint. Upon leaving Preston Lodge the party entered brakes and drove to Dairsie Church, three miles distant, where they were received by the Rev. Robert Wright and Mr. Frank Christie. The church was built by Archbishop Spottiswoode in 1621, and is a fine specimen of the quaint ecclesiastical architecture of that period. The founder had a burying vault prepared for himself directly underneath the altar, but as in the case of the Montrose vault in St. Giles, it was utilised for heating apparatus. The Archbishop was buried underneath a flat stone at the entrance to the church. The exterior of the church remains entire, and is surmounted by a remarkable octagonal turret, but the interior has been stripped of all its old features. Dairsie Bridge, said also to have been built by Spottiswoode, but which is mentioned in documents of a much earlier period, was viewed before the party proceeded to the ruins of Dairsie Castle. Ceres Castle was next visited. In an outhouse rapidly going to ruins there are two coffins containing the remains of John, twentieth Earl of Crawford and his wife, who died in the middle of last century. The Earl's body is embalmed, and sealed in a zinc case. The outer coffin is of oak, covered with green velvet and mounted with brass, and the lid is unfastened. The remains of the Countess are sealed in a lead case. A square box of velvet-covered oak, containing the Earl's heart, lies between the two coffins. The party were informed that until a few years ago the remains of the Earl and Countess lay exposed to view, anyone who desired being at liberty to lift the coffin-lids. The gravedigger assured them that before the body of the Countess was finally encased in zinc, someone "put the banes a' back in their richt places." A visit was next paid to Craighall Castle, about four miles from Dairsie. Mr. Thomas Ross (of Messrs. M'Gibbon & Ross), whose researches in connection with the castellated buildings of Scotland eminently qualified him as leader for the day, gave some interesting notes regarding these ruins. The castle, now the property of Mr. Hope of Luffness, was probably built about the end of the sixteenth century in the style then current in Scotland. At the end of the seventeenth century a centre of considerable richness was added to the front in the style of the Renaissance. A gatehouse, still entire, was built early in the seventeenth century. Struthers, about three miles from Craighall, was next visited. The ruins are of considerable extent, and the place is interesting with its associations with "Sir David Lindsay of the Mount, Lord Lyon King of Arms." Scotstarvit Tower was opened to the party by permission of Mr. David Wemyss, of Wemysshall, through Mr. David Osborne, writer, Cupar. The tower is a perfect example of a Scottish keep of late erection, having been built about the beginning of the seventeenth century. It is in good preservation, but uninhabitable. Here Sir John Scott wrote his well-known treatise, "The Staggering State of Scottish Statesmen." From the top of the tower a splendid view was obtained. Cupar was reached again at a quarter to six o'clock, when the company sat down to dinner in the Royal Hotel, under the presidency of Mr. W. W. Robertson, of H.M. Board of Works. Dr. Rowand Anderson officiated as croupier, and amongst others present were:—Professor Struthers, Mr. J. Hippolyte Blanc, A.R.S.A.; Mr. John M'Laren, Dundee; Mr. D. Barclay and Mr. White, Glasgow Architectural Association; Mr. James Bruce, W.S.; Mr. Jamieson, solicitor, Cupar; Mr. Thomson, banker; Mr. James B. Dunn, Mr. John Watson, Mr. Thomas Ross, Mr.

Andrew Muirhead, Mr. Kirkwood (of Messrs. Clark & Co.); Mr. W. T. Russell, surveyor; Mr. T. Fairbairn, hon. sec.; Mr. Wallace and Mr. Giles. A number of toasts were proposed, and the chairman referred to the loss sustained by the society through the death of Mr. M'Lachlan, their leader at their excursion a month ago. The party afterwards returned to Edinburgh, which was reached about half-past nine.

NEW BUILDINGS.

London.—A new Board School in Greenwich Marshes was opened on Monday, May 29, by Mr. J. R. Diggle, M.A., chairman of the School Board for London. The school is erected in Blackwall Wall Lane, built to accommodate 805 children, but with "halls" large enough for a future extension for 1,200 children at a small additional cost. It is built from the design of Mr. J. T. Bailey by Messrs. Treasure & Son, builders.

London.—The head offices of the Capital and Counties Bank, Limited, situated at the corner of Threadneedle Street and Bishopsgate Street Within, E.C., have been reopened in their entirety after undergoing extensive alterations, additions and entire refitting. The original premises occupied the old site of the church of St. Martin Outwich, demolished some years ago, but they have been extended to include the two adjoining properties, Nos. 37 and 38 Threadneedle Street, the whole now forming one building. The basement, ground floor and portion of the first floor are occupied by the bank; the remainder of the premises is arranged as offices for separate tenancy, good accommodation for caretakers being also provided. The original building had been considerably restricted by surrounding rights of light, and, while these have been modified by negotiation, their influence has still been felt to a great extent in the present operations. The entire work has been carried out by Messrs. Patman & Fotheringham, under the direction of the architects, Messrs. Kidner & Berry.

Edinburgh.—At the meeting of the Edinburgh Dean of Guild Court Professor Patrick Geddes was granted authority to erect two blocks of buildings, one to the east of Ramsay Lodge, and the other between Ramsay Lodge and the houses in Ramsay Gardens, and also to make alterations on Ramsay Lodge. This pile of new buildings, designed by Messrs. Sydney Mitchell & Wilson, architects, will occupy one of the most prominent sites in Edinburgh, looking northwards as it does over Princes Street, and westwards over the slopes of the Castle Hill. The westmost portion of the block will contain houses in flats. The eastern portion of the block—which includes Ramsay Lodge—is to be used as a students' home or University settlement. It will contain large dining and recreation halls, and numerous rooms for occupation by students. The buildings are designed outwardly in a varied and picturesque style, intended to recall the past glories of old Edinburgh. At the extreme north-west corner is a circular tower, measuring 85 feet from the ground to the top of the vane which crowns it. This tower is constructed from base to summit of a pale red sandstone. It is divided by moulded string-courses into four unequal stages. The windows in it are few until the top is reached, where there is a range of them separated by stone pilasters, thus forming a lantern. The effect of this tower is to give great solidity to the angle of the building. Abutting on this tower to the eastward is a gable, which, beginning in stone at the ground, projects forward at the second storey, and is carried up with ranges of windows between wooden pillars in a manner which recalls the famous house which formerly stood at the corner of the West Bow. Next this comes a plain wall pierced irregularly with windows and covered with rough cast. Next, again, comes the familiar octagon bay of Ramsay Lodge, now raised in height a storey, and crowned with an open balcony and high-pitched roof. This is succeeded by another gable carried up in stone through four storeys, and then continued in rough cast. In this portion of the building is the recreation hall, which is marked externally by four bold two-light mullioned windows, which run in height through two storeys. In the upper portion of this gable is a quaintly corbelled-out oriel. It is intended finally to make some changes on the roofs of the houses in Ramsay Gardens so as to bring them into harmony with the new buildings. It is not possible to note the numerous little balconies, corners and brackets which occur here and there throughout the buildings and help to give them an old-world air.

Arundel.—The oak roof of the nave of the fine old church at Arundel has been carefully examined and reported on by several well-known architects, and owing to the ravages of worm the main timbers have been condemned as unsafe. The work of entire renovation has been placed in the hands of Mr. Geo. H. Fellowes Prynne, F.R.I.B.A., of Westminster. The roof, which was restored by Sir Gilbert Scott some seventeen years ago, will be carefully copied in detail and renewed in English oak, only such timbers as are found to be untouched by worm being reused. The contract has been undertaken for the sum of 1,058*l.* 9*s.* 7*d.* by Mr. Burrell, builder, of Arundel.

Registration of Plumbers.

Sir,—You will, I feel sure, pardon me trespassing upon your space to state, at this opportune time, in my opinion, a few reasons why plumbers should approve of and support the Bill for Registration of Plumbers now before the House of Commons. Plumbers ought to pass resolutions approving of the Bill, and should obtain the support of trades councils and similar bodies to the measure, and through such bodies solicit the support of members of Parliament to the Bill.

Plumbers (this does not mean any who appropriate the title of plumber) are, and always have been, proud of their trade, and their efforts have always been to execute work of a sterling and reliable character, and of credit to the trade. But to some extent these desires during recent years have been overshadowed and placed under a ban by sanitary authorities and such like bodies through the jerry-work permitted, and in many cases carried out by incompetent tradesmen, under the supervision of the bodies who afterwards condemned the genuine tradesman for what he was not guilty of. It is probable, had a law been in existence twenty years ago similar to the one proposed, the sanitary authorities referred to would not have placed implicit faith in anyone who took unto himself the title of plumber. The sanitary authorities would have been able to protect themselves and those they were acting for by being able to demand the sign of qualification, *i.e.* the Certificate of the Worshipful Company of Plumbers, or some such body appointed by law to examine and determine who are qualified workmen.

Ample evidence of the interest and desire of plumbers to maintain their position for excellent workmanship is shown by the self-denial exercised by plumbers in teaching, in practical classes, those who are apprenticed or have been apprenticed to the plumbing trade. In all cases the results have been very gratifying where apprentices and journeyman plumbers only have been permitted to attend the classes.

In some cases these classes have been carried on entirely by the working plumbers, who have been seriously hampered for funds. In my opinion, wherever a number of practical and experienced workmen in any trade are willing to undertake the training of the rising generation, or the improvement of those who have served their apprenticeship, the technical educational authorities, after satisfying themselves of the genuineness of the effort, should assist in furtherance of the scheme, instead of expending large sums in buildings, creating salaried officers, and undertaking to teach any and every one any trade desired, the result being barren and generally disappointing. If it is necessary that anyone intending to be a lawyer or doctor should be trained in classes specially appointed, and the students not hampered by those who have no intention of following such professions, it is much more necessary that there should not be any drawbacks or hindrances to the teaching and studies of anyone in classes in connection with the building trades, seeing the very limited time that is at their disposal.

I trust that the sanitary authorities—no matter what name they are known by—and members of Parliament will co-operate with and assist plumbers in securing a legalised system of registration, whereby the public may be enabled to secure the services of plumbers, and the pretender relegated to limbo—a punishment richly deserved—for the suffering and misery caused in numerous cases, and the unjust stigma that is attached to the plumbing trade through his antics.

It is a matter of surprise and regret to plumbers (employers of practical plumbers I mean, and workmen), to find that opposition to the Bill is raised by ironmongers and master builders. I cannot understand their opposition to the Bill, because in all cases of evidence it was admitted that such a safeguard is necessary to protect the public. At the same time the ironmongers and builders are using every means in their power to prevent the establishment of this remedy. Their only reason, so far, is that it would create a monopoly in the plumbing trade. Let us test the case by analogy. Any vendor of patent medicines must, if he has not obtained a diploma as a chemist, employ one who has secured such mark of ability. Is not the vendor of patent medicines in a similar position to that the master builder or ironmonger would be in if the Bill became law? It does not need a very keen search to find a host of such vendors, who are not qualified chemists, but employ men who are, therefore clearly proving that in this case the qualified chemist has not obtained a monopoly, although possessing the necessary qualification to protect the public. A similar analogy exists in the case of marine engineers; although they possess the sign that they are qualified to construct, build and repair an engine, the firms that have been noted for the manufacture of engines for generations continue to make them, and their business has not decreased.

It is only fair that in all cases where a man proves his ability that he should be entitled to hold the mark of his ability and not his employer; to give an employer, who may be purely a capitalist, a sign whereby the public would be deceived by expecting the capitalist possessed special knowledge would be dishonest, equally as dishonest as certifying that a plumber was a capable and competent joiner, mason or bricklayer. I know that a large number of plumbers work, and in many cases prefer to work, for master builders and ironmongers. And I may add that the only reason why the present system of registration has not been more generally adopted is, because of the number of employers and men who have been registered at the beginning of the scheme who had not the slightest claim to be registered beyond the fact that they either employed plumbers or were known by the name of plumbers prior to 1886.

Plumbers objected to such men being registered, but it was essential that such should be registered at the establishment of the movement.

Let us see how far a monopoly would be created. I must use another analogy. Anyone can treat any person who is sick and cut and carve any limbs, and the fact that it is necessary for a doctor or surgeon to pass an examination before he can practise does not prevent anyone dealing with diseases, &c. (the law prevents them appropriating the title of doctor or surgeon or chemist), and in case of fatal results through inefficient treatment they are liable to punishment by law.

This bill if passed, and I hope it will, does not prevent anyone interfering with the sanitary arrangements of a house, &c.; it is only intended to prevent them attaching to themselves the title of plumber, and to punish them if the work was found defective.

The charge that ironmongers have in many cases been engaged to rectify the work of qualified plumbers requires the usual quantity of salt, and till proof is forthcoming must be attributed to excited imagination, or the hope that the statements will be accepted as true.

Plumbers were fairly free from the attentions of comic papers, &c., till the jerry builders and others usurped the position of the master plumber, who, being a practical man, was jealous of his credit, his reputation and business depending entirely upon the quality of workmanship, and failures then were principally due to the weather and strength of material used.

I appeal to all interested in the advancement of sanitary science, in efficient workmanship, to assist in carrying the bill for the registration of plumbers, and prevent the robbery and jobbery that has been perpetrated and carried on in the name of the genuine plumber. I am yours, &c.,

GEO. B. CHERRY, General Secretary,
United Operative Plumbers' Association of Great Britain and Ireland.

GENERAL.

Professor Kennedy, of London, has been appointed engineer to the Corporation of Edinburgh in connection with the installation of electric light which the Council propose to introduce into the city.

The Private View of the Summer Exhibition of Water-Colours at the Dudley Gallery takes place to-morrow (Saturday).

A Pavement of Roman mosaic has recently been laid in the entrance-hall and principal corridors at the Manchester Art Gallery. The design is of a strictly classical character, in harmony with the architecture of the building. The work has been executed by Messrs. J. & H. Patteson, Marble Works, 36 Oxford Street, Manchester.

The Feoffees of the Common Lands of Rotherham have made a grant of 750*l.* towards the erection of a children's ward connected with the Rotherham Hospital. The extension will be known as the Feoffees' Children's Ward.

Mr. Henry Boys has offered to give 100 guineas for building a tower for the new church of St. Paul's, Walsall, providing that nineteen other persons will contribute a like sum. Independently of the tower, the present works will cost about 10,000*l.*

Mr. Mavor, architect, is to report to the Aberdeen School Board on proposed alterations to be made at Broomhill Place School.

At the Annual Meeting of the Montrose Antiquarian Society the following office-bearers were elected:—President, the Right Hon. the Earl of Southesk, K.T.; vice-president, Mr. Edward Millar, of Rossie Castle; secretary, Mr. R. Barclay, of Inchbrayock; treasurer, Mr. A. Dickson, solicitor.

In a Limited Competition for a proposed new church at Westham, Weymouth, the plans submitted under motto "Pro Aris," by Mr. Geo. H. Fellowes Prynne, F.R.I.B.A., were selected by the arbitrator, Mr. William White, F.S.A., and have since been duly adopted by the committee.

The Statue of the late Professor Fawcett, erected by Sir Henry Doulton in Vauxhall Park, South Lambeth, has been unveiled.

The Architect.

THE WEEK.

THE judgment of Mr. Justice CHITTY in respect of the application to sell the HOPE collection of pictures by Dutch and Flemish masters will not probably gratify the dealers, but it is important for many reasons. In the first place, such a sale would be like the erasement of a coat-of-arms. The HOPES may not figure as nobles, and they are allied to the English aristocracy. But their Batavian origin is a matter of record, which cannot be disputed. THOMAS HOPE was not ashamed that his family were Dutch merchants. BERESFORD HOPE would probably have refrained from "sinking the ship" if he could be assured that one of his race wrote a little book about the necessity of an ornate ritual. The pictures in question were evidence that heredity prevailed among the HOPES as among other families, and that they continued to have a passion for pictures by Dutchmen which represented Dutch scenes. But a new representative has other views, and the pictures are as scorned as if they resembled the old accounts of the house which related to dried fish. So application was made for authority to get rid of the masterpieces. It was made out that, notwithstanding all that was done by various architectural HOPES in building, there was no shelter for the pictures, and they had to be sent to the South Kensington Museum. A dealer took pity on their homeless state, and offered no less than 80,000*l.* for the privilege of protecting them. Why should not his offer be accepted? The Settled Land Act of 1882 is an obstacle. Mr. Justice CHITTY could not see how the pleasant domain of Deep Dene at Dorking was to be benefited by the sale of the pictures, and he wisely declined to approve of the arrangements. In one sense it is an advantage for pictures to be dispersed, but the HOPES were zealous for architecture, and on that account we wish to see their family records preserved, and the pictures were among the most notable of them.

MANY of our readers will remember the outcry which was raised when WILLIAM BURGESS proposed to introduce marble slabs as part of his scheme for the decoration of St. Paul's Cathedral. It was supposed to be an act of *lèse-majesté* against the genius of architecture which all men of good taste were expected to consider as an unpardonable crime. Time brings its revenges. Anyone who will now visit St. Paul's can observe that BURGESS'S idea is being realised on a partial scale and under different conditions. His proposal has, however, been salutary in other ways. Is not the use of marble in all sorts of buildings due to it? Veneering was supposed to be dangerous in all shapes, and thick slabs of precious marble were classed with the "solid mahogany" and "solid walnut" of the cheap furniture makers. Common sense however prevailed, and it was perceived that it was absurd to treat lovely marbles as if they were building stones. When used as BURGESS proposed, it was feasible to embellish the interior of buildings in the worthiest manner. Marble used, according to pseudo-true principles, meant ruin. When we find that many people in Sheffield want to have a marble lining for their staircase we must admit that BURGESS'S influence is still operative, and in course of time we may hope to see many more of his ideas realised.

THE Royal Cambrian Academy is undoubtedly one of the most successful of the provincial painters' societies, and it is gratifying to learn that out of the exhibition at Conway which is now open several pictures have been purchased. Mr. CLARENCE WHAITE continues to serve as president, and his influence and example have aided in many ways to insure the efficiency of the Academy. At the beginning of the present year the Cambrian Academy suffered a great loss by the death of Mr. LAURENCE BAULES, the honorary secretary, who held that office from the first. The Academicians have just elected Mr. PAIN DAVIES as his successor. Mr. SWINFORD WOOD is the new treasurer; Mr. CUTHBERT GRUNDY and Mr. E. A. HORBURY will serve, with the president and treasurer, as trustees of the Cambrian Academy.

It is accepted generally that the strength of a chain is determined by the weakest link, but the discovery of that member is no easy task. A flaw in a link caused much injury on Monday to a statue in Liverpool. In the Royal Institution of that city, among the works of art taken over by the Corporation was a statue of WILLIAM ROSCOE, whose histories of LORENZO DE MEDICI and LEO X. were among the first indications that the interest of the Renaissance was about to be appreciated. The volumes also made it appear that the pursuit of scholarship could be combined with mercantile business. ROSCOE did much for the elevation of Liverpool, and well deserved a statue. The commission for it was given to CHANTREY. A committee of the Corporation decided to place the statue in St. George's Hall. There was no place for it in the great hall, but a good position was assigned it in the north hall or vestibule, where it would have a window for a background. The statue was safely removed from Colquitt Street, the low pedestal was fixed, and on Monday the hoisting of the figure was commenced. The necessary space was almost traversed when a link in one of the chains succumbed to the strain. There was apparently no provision in the shape of a check, and the mass fell. A part of it sank through the sandstone pavement to the depth of 12 inches. The flags must have had some slight elasticity, or otherwise the figure would have been broken in several pieces. The neck being the weakest part gave way, but with the exception of the nose the head has sustained slight damage. The nose must be renewed. A part of one of the shoulders and a foot, with a few splinters from the drapery, have been removed. The marble, as can be seen from the fractures, is close-grained, and undoubtedly very tough. Besides, ROSCOE was represented seated with his hands on a book, and hence there was more solidity of mass than would be possible with a standing figure. The accident is to be regretted, but there will be little difficulty in repairing the damage. It would be fortunate if antique figures were found with no imperfections. The whole of St. George's Hall is dimly lighted, and in the north vestibule the repairs would not be observed if they were not pointed out by the compilers of future guide-books. The statue is not a great work—it will not bear comparison with the sculptor's *James Watt*—and the accident will impart to it a new interest. Liverpool is, however, the last place where one would expect a defect in a hoisting operation.

ONE of our correspondents informs us that an opportunity for studying a problem in acoustics is now afforded at Blackpool. The pavilion on the South Pier is in the hands of the builders. There are several lines of scaffold poles, and the whole of the upper part of the hall is covered with a scaffolding of planking. In other words there is obstruction to sight on all sides. It is remarkable, however, that the acoustic properties of the pavilion have been vastly improved. Whenever a concert is held there every note tells. There is a large band, and if the members are to be heard at their best it is amidst the forest of timbers; this fact is as evident in solos as in concerted pieces. Vocalisation also seems to be improved. It would appear as if currents of sound correspond with currents of air in ventilation and become more efficient by means of some agency to guide and discipline them. There is little likelihood that theatres or concert-halls with rows of pillars will ever find favour with the public, but after some experience of them amateurs might prefer them. Travellers are aware that in foreign churches, like the cathedral of Antwerp, which are cut up into several divisions, the musical performances have a charm that could be called novel.

THE Manchester School Board have decided that the following architects be invited to send in competition designs for School Board offices to be erected in Chapel Street—Mr. HENRY LORD, Messrs. ROYLE & BENNETT, Mr. HENRY E. STELFOX, Messrs. W. WADDINGTON & SONS and Messrs. WOODHOUSE & WILLOUGHBY—and that the conditions drawn up for the competition be approved and adopted, viz. that the successful firm should be paid 5 per cent. on the cost of the building, and the unsuccessful competing firms 10*l.* each.

NOTES, PRINCIPALLY ON ENGLISH "GEOMETRICAL DECORATED" WINDOWS.

II.

BY A CORRESPONDENT.

THOUGH the majority of Gothic windows certainly have lights of equal width, there are many exceptions to this rule. In the lovely nine-light east window of Carlisle Cathedral, in the seven-light one to the east end of Guisborough Abbey Church, and in that of five lights to the south transept of Northborough Church, Northants (the latter previously alluded to for another reason), the central lights are wider than the others, and with telling effect, as the two central mullions are thicker, with an extra order. In the case of the six-light east window of Raunds Church, Northants, it is somewhat different, there being an even number, and the second and fifth lights are the wider. As a general rule, therefore, there is no reason to depart from the more usual practice of the Middle Ages.

Let us now proceed, upwards, to the commencement of the tracery, having considered various points below that line. It is unnecessary to say much about the treatment of the transome, which belongs to a style later than that now being touched upon. But in the elegant Early Decorated four-light west window of Howden Church, Yorkshire, a traceried transome was inserted in the Perpendicular period with excellent result. As the height from sill to the springing-line is nearly 23 feet, the transome seems to strengthen and bind the composition together, without detracting in any way from the majestic proportions. In fact, it may be said the transome serves like a milestone, and as a measure enabling the spectator to realise the great height, in the same manner as the interposition of screens in a church undoubtedly increases its apparent length. The writer, in a very large church of which he was the architect, endeavoured to carry out the principle of a transome in a long window at the west end of the nave, the general style of the building being based on that of the thirteenth century. A square enriched panel, not pierced, takes the place of a transome, and serves to break the great length of the window, the *outer* mouldings of which, externally, are continuous from sill to springing-line of arch. In the gables to churches of considerable height there is certainly abundant precedent for two tiers of windows, with a string-course between them, even where no triforium exists. But the writer has felt that in modern parish churches this treatment suggests to the outsider two storeys internally, or, in other words, a gallery, and so has hesitated to adopt it.

In France and Germany it is quite common for the tracery to start considerably below the springing-line of the window-arch, or, to put it in another way, the latter is highly stilted. Of course this gives more room for the tracery-head and space for a large central circle, but at the sacrifice of grace. The two-light windows to the cathedrals of Noyon and Bourges, France, are examples of what is deprecated. In England, however, this excessive stiling of the window-arch is happily of more rare occurrence. In the great example at Howden Church, previously mentioned, the arch is slightly stilted with good effect, and in a window at Billingborough Church, Lincolnshire, much more so. But owing to the absence of a central circle and the elegant arrangement of the tracery in this latter specimen, as well as from the length of the window, the effect is good. At Northfleet Church, Kent, is a two-light example, and the arch is much stilted in order to get in a huge circle enclosing a quatrefoil. This gives it a singularly un-English appearance without any compensating feature. For in this case the lower part of the circle in the tracery is some inches below the springing-line of the window arch.

Having made these comments on the employment of tracery below the springing-line, it will be well to touch upon the very opposite practice of carrying up one or more lights above the same. Of late years this has been much more commonly done by architects, with the idea, probably, of novelty. For there can be no comparison as regards beauty between the complete tracery-head from springing-line up to apex of window-arch and the incomplete one. The best use of such is to place them in those positions where the admission of the largest

amount of light is of importance, and where the space available for a window is limited. That with three lights at Milton Abbey Church, Dorsetshire, is an instance of the type alluded to. Another effort at novelty in the design of modern windows of Flowing Decorated character is the carrying up of two of the mullions through the tracery-head, home to the arch above, and treating these as "butssets," to coin a word. Or, in other instances, some of the mullions are planned as piers, containing figures in canopied niches. In such as these the tracery-heads get cut up into three or more divisions, and the character of the windows of the Middle Ages is quite lost. The design, in fact, resolves itself rather into three windows more or less partly connected. For it has been said that one of the essentials of a really fine traceried window is the difficulty in dissecting it and making a smaller one out of its parts. There is a certain amount of truth in this remark, but if its principle was admitted as absolutely true, it is to be feared many much-admired windows would be condemned. In fact, it is obviously not practicable to carry out the principle *in toto*. In a three-light window there often comes an awkwardness and appearance of weakness when the mullions are carried up vertically half-way or more between the springing-line and the apex of the arch. This occurs in the space left at the sides, where the mullions commence to form a part of the tracery and converge towards the centre. This illustrates in another way, beyond what has been previously mentioned, the undesirability of running up vertical lines into tracery unless it is done on a regular system, such as that during the great Perpendicular period. There is another weak form not unfrequently found in the heads of lights under the tracery of a window that is not so apparent or objectionable if the tracery is of good substance. This is what Lord GRIMTHORPE, when Mr. BECKETT DENISON, in his "Lectures on Church Building," published many years since, called the "broken-backed" cusp, *i.e.* a trefoil head to a light without the protecting arch over it; or in other words, not trifoliated. He very properly condemned this feature, and little as the writer in general agrees with the architectural views of this noble lord, he can approve in this instance. Though the Decorated two-light window in the chancel of Chartham Church, Kent, is charmingly original in design and has much elegance, it has somewhat the same fault just commented upon, the construction for stonework being essentially weak, and therefore not good. A four-light window in the north aisle of Whitby Abbey Church, of the Early Decorated period, has a traceried head of most remarkable, though beautiful, character, a little resembling the last-named example in some of its features, but treated constructionally in a better manner. But as a general rule the simpler forms are the most telling, as those which are out of the way require much skill to become harmonious, and more frequently than not fail to please the eye. Exeter Cathedral possesses, of course, a wonderful collection of four-light and five-light Early Decorated windows of very diverse design, but all with the roll-moulding taking the place of the more customary fillet as the guiding line. It is stated that there are twenty of the former and forty-one of the latter. As these windows are so well-known it is superfluous to comment upon them. But there are other examples of the Middle Ages which, though showing originality in design, are yet eccentric in composition or positively ugly, without any grace to redeem their oddity. Such a one is the four-light Decorated east window to Evington Church, Leicestershire, where the tracery-head is cut up by cusped square forms, and by the mullions prolonged into the window-arch in such a manner that all the lines seem in conflict, the one clashing with the other. Scarcely less objectionable is a Geometrical Decorated three-light window at the church of Stanton St. John, Oxfordshire, which looks like Reticulated tracery transformed from flowing into straight diagonal lines, resulting in lozenge-shaped openings, well cusped, but much at variance with the outline of the window-arch, the general effect being decidedly ugly. The acme of debased Flowing Decorated tracery is probably reached in a four-light window at Melrose Abbey, in which there is not a single redeeming point, the forms being very poor, the mullions and tracery also extremely thin. A Decorated window in the south chancel aisle of Cartmel Church, Lancashire, has

some noteworthy forms in the tracery, a very small foil not much wider than a cusp-point being used between much larger ones. This affords a pleasing variety.

The treatment of the space between the springing-line and the apex of the window-arch, the most important part, has now been arrived at after a gradual climbing up. What a vast subject for comment does this present! It is very desirable to study the best principles on which the composition of the tracery should be based. Though EDMUND SHARPE published his excellent work on "Decorated Windows" upwards of forty years since, some of the words he then wrote may be profitably quoted at the present day. Speaking of Late Decorated examples, he remarked, page 92:—"The study of the architect seems principally to have been, as in the late Curvilinear period, to fill the window-head with a variety of elegantly-formed proportions, rather than to produce unity of design or a striking and beautiful whole." Although our authority was thus speaking about the work of the Mediæval men his warnings can equally well be applied to some of the productions of modern architects. In some windows of the present time, founded on those of the Flowing Decorated period, this "unity of design" appears to have been lost sight of. A great tracery-head is filled with much-varied forms, elegant in themselves, not struck in with compasses, and having all the perforations of much the same superficial area. This is monotonous, and although it may possess some amount of quiet beauty, has no *grandeur*. It is, moreover, rather hard on the glass-painter, who is puzzled to know how to fill in these small spaces, and therefore forced to remain content with the lights only for his subjects. Now, if there is a good-sized arch in the tracery-head that can be foliated and sub-foliated to a moderate extent in order to bring it into harmonious proportions with the immediate surroundings, the difficulty vanishes. The magnificent Geometrical Decorated window at the west end of Howden Church, Yorkshire, is a good instance of what is meant. Instead, however, of the large central circle is an equally large opening—a spherical square set diamond-wise, so to speak, for the lower half of it is produced by the inversion of the window-arch. There is a great quatre-foliation with sub-trefoil foliation, all in excellent proportion to the much smaller openings in the lower part of the tracery. It will not be out of place at this juncture to allude to the beautiful composition outside the window itself in this example. The crocketed and finialed pediment with its pinnacles, the ornamental paneling and sculptured figure in niche, in the space between the label to the window of the pediment, also the elegant panelling beyond the jambs—all these decorative adjuncts help to emphasise the window, while the tracery of the latter is kept together intact and not cut up as in some of the modern specimens just commented upon.

(To be continued.)

BIRMINGHAM AND MIDLAND INSTITUTE.

ON Saturday last, the *Birmingham Post* says, about thirty members of the Archæological Section took train at New Street Station for Salford Priors, where they proposed to begin the first field meeting of the present year. Upon arriving at Salford the party proceeded in the direction of Cleeve Mill, passing some picturesque thatched cottages and the fine old church of Salford. At the church the Rev. B. Davis (vicar) received the party, and pointed out the chief objects of interest. The church contains specimens of all styles of architecture, from the round-headed Norman to the graceful Perpendicular. There is an ancient parish chest fashioned out of the solid trunk of an elm tree. Here is the burial-place of the Bushell family, to whom the manor belonged in the seventeenth century, and there is a monument to "Thomas Bushell, son of Anthony Bushell, Lieutenant-Colonell for His Majesty Charles the First. He died April 17, 1704, in the 50th year of his age." In the churchyard there is a stone commemorating a venerable worthy who died at the patriarchal age of 309, but the village chiseller probably intended it for 30 and 9. This same artisan, or one of his compeers, is also answerable for a curious carving of Adam and Eve. A winding path beneath the shade of lofty elms brought the party to the old manor-house of Cleeve, where the visitors were received by Mrs. Holtom and family. The delightful old mansion was explored in every part. The extraordinary avenue of yews, 10 or 12 feet high, cut into shape and called the Twelve Apostles and the Four Evangelists; the great manor barn, the carved and mullioned windows, the panelled rooms, the antique family portraits (the

earliest dating from the time of Elizabeth or James I.), the manor court-room, and the chamber where the officer of the Prior of Worcester and his successors was wont to appoint the ale-tasters, rat-catchers, and other functionaries of the manor, as well as to collect the rents and fines due to the lord, all received attention. Even the haunted chamber was visited and the secret of the family hiding-place revealed to the visitors. Here a murder had been committed long ago, and here probably Thomas Bushell, servant and disciple of Lord Bacon, hid himself for more than a year from the Parliamentarians. Access to the hiding hole is obtained by taking up the floor of a little chamber on the upper storey, and the fugitive could bolt himself in in such a manner that the door of his retreat was as firmly fixed as the rest of the flooring of the chamber. Thomas Bushell was much given to mining speculations, and became the farmer of the king's minerals in Wales. He cut through mountains, carried air through them by pipes and bellows, worked for years in draining water, and established a mint for the use of the king during the Civil Wars. He entertained Charles and his Queen in Oxfordshire, where he cut a rock into curious shapes, caused automaton hermits to ascend from the ground with poetical addresses, and caused a sonnet to be sung by some invisible agency from the leg of a table. He died in 1674, more than 120,000*l.* in debt. In the year 872 King Ethelred gave Cleeve to the Priory of Worcester. A bailiff and a collector lived at Cleeve, and the chief tenants furnished the monastery with a boar, money, &c., while the vicar presented the prior with a peahen as a New Year's gift. The Bushells are descended from Sir Alan Bushell, who died in 1425; their names appear in Cleeve register in 1604. Robert Bushell married the daughter of Sir John Fettiplace, Bart., and their son Charles succeeded to the estates and name of his maternal grandfather, and one of the last of the Fettiplaces was buried at Cleeve in 1799, and his escutcheon hangs over the hall door of the manor-house.

After the house had been viewed Mrs. Holtom regaled the visitors with strawberries, and the party left for North Littleton, where they were met by the Rev. F. S. Taylor (vicar), who explained the chief objects of interest in the church and great barn built by the monks of Evesham Abbey five centuries ago, permission to view the barn having been kindly granted by Mr. William Lidsey. From North Littleton the way led by field paths to South Littleton, across ridge and furrow, one of the best examples of Saxon cultivation left in this county. Here the "yard lands" are distinctly marked, and the ridges are yet high above the furrows. The Vicar and Mrs. Taylor received the archæologists, and hospitably entertained them to tea on the vicarage lawn, a most delightful spot, shaded by cedars and Wellingtonias, and fragrant with the perfume of many roses. After a walk of nearly four miles rest and refreshment were most acceptable. After tea a move was made in the direction of the church, where the Rev. F. S. Taylor gave a graphic description of the history of the sacred building. The door, font and some of the walls are of early Norman work, but the foundation of the church is considerably older, perhaps dating from Saxon, or even Romano-British days. One of the chancel windows is carved out of a single stone; there are fragments of ancient glass, a fine decorated porch, interesting carvings and encaustic tiles—the latter of the usual Worcestershire type, similar to those made in the fourteenth century at Malvern and Droitwich, but some of them differing in design. One ornamented with the five wounds of our Lord was especially interesting, and scarcely less so two shields with the arms of the De Clares, Earl of Gloucester, and the arms of Gloucester Monastery. An old mansion opposite the church was also visited, and from the roof some of the party obtained a fine view of the surrounding country, and examined the curious mechanism connected with the weathercock. Carriages then arrived, and the party were taken to the Crown Hotel at Evesham, where supper was provided. After supper Abbots Lichfield tower and the abbey ruins were inspected, and then the party assembled at the station and returned to town by the 8.50 train, having spent a most delightful half-day in the country under most favourable circumstances.

GLASGOW ARCHITECTURAL ASSOCIATION.

AT the meeting of this Association a paper was read by Mr. John Rogerson on "Woods." Dealing chiefly with the pine series, an account was given of the different varieties, their qualities and defects, with a comparison between log and deal timber in reference to their use in building. The various ports of shipment were also referred to as an indication of quality and as a guide to selection. Touching briefly on a few of the less important timbers, kauri pine was noticed as having come largely into use recently, and as being very suitable for some purposes, although perhaps not adapted for joiner-work generally. The discussion was opened by Mr. Charles Gourlay, and at the close a hearty vote of thanks was awarded the lecturer.

SKETCHES AT ALKMAAR, N. HOLLAND.

WE give in continuation a few odds and ends of old work at Leyden and Haarlem, from sketches by Mr. F. T. W. Goldsmith, made in 1886—two from the Town Hall, Leyden, and two from Haarlem, some houses near the Amsterdam Gate and a fêche on the roof of Jans Kerk.

The other sketch is an old church near Alkmaar—name of the village forgotten. The church, as will be seen, has suffered rather badly at the hand of the invader, until at present the only portion used is the part crowned by the inevitable turret.

OLD CHURCH NEAR ALKMAAR.

SITE OF AN OLD HOUSE IN EDINBURGH.

THE Lord Provost's Committee of the Edinburgh Town Council lately had under consideration a motion by Dean of Guild Miller, in connection with the commemoration of the site of the house of Sir Simon Preston of Craigmillar "forenent the Cross," in which Queen Mary is said to have slept after her surrender to the Confederate Lords at Carberry Hill, June 15, 1567. The committee had before them a memorandum on the subject prepared by ex-Bailie Miller, showing on an examination of numerous historical records that the house in question stood partly on the site of the present entrance to the Royal

Exchange, and partly to the west of it. After talking over the matter the committee resolved to recommend that there should be placed on the west side of the entrance to the Royal Exchange an inscription in these terms:—"On this site stood the mansion of Sir Simon Preston of Craigmillar, provost of the city of Edinburgh, 1566-67, wherein Mary, Queen of Scotland, spent her last night in Edinburgh (June 15, 1567), after her surrender to the Confederate Lords at Carberry Hill, from which mansion she was conveyed to Holyrood on the following evening, and on that evening sent off to Lochleven Castle as a State prisoner by the Confederate Lords."

THE INSTITUTION OF CIVIL ENGINEERS.

THE following is a detailed list of the awards made for original communications submitted during the past session:—

For Papers Read and Discussed at the Ordinary Meetings.

1. A Telford Medal and a Telford Premium to Peter William Willans,* M.Inst.C.E. (deceased), for his paper on "Steam-Engine Trials."
2. A George Stephenson Medal and a Telford Premium to Edward Hopkinson,† M.A., D.Sc., M.Inst.C.E., for his paper on "Electrical Railways: the City and South London Railway."
3. Telford Medals and Telford Premiums to Mathew Buchan Jamieson, Assoc.M.Inst.C.E., and John Howell, for their joint paper intitled "Mining and Ore-Treatment at Broken Hill, New South Wales."
4. A Watt Medal and a Telford Premium to John Rigby, M.A., for his paper on "The Manufacture of Small Arms."
5. A Telford Premium to George Edward Wilson Cruttwell, M.Inst.C.E., for his paper on the foundations of the two River Piers of the Tower Bridge."
6. A Telford Premium to Walter Pitt, M.Inst.C.E., for his paper on "Plant for Harbour and Sea Works."

For Papers Printed in the Proceedings without being Discussed.

1. A Telford Medal and a Telford Premium to George Shattuck Morison, M.Inst.C.E., for his account of "The River Piers of the Memphis Bridge."
2. A Telford Medal and a Telford Premium to Robert Gordon, M.Inst.C.E., for his paper entitled "Hydraulic Work on the Irawady Delta."
3. A Telford Medal and a Telford Premium to Alan Brebner,‡ B.Sc., Assoc.M.Inst.C.E., for his paper on "Relative Powers of Lighthouse Lenses."
4. A Watt Medal and a Telford Premium to Herbert Byrom Ransom,‡ Assoc.M.Inst.C.E., for his paper on "A Method of Testing Engine Governors."
5. A Telford Premium to George Morrison Barr, M.Inst.C.E., for his account of the "Improvement of the Entrance of Otago Harbour, New Zealand."
6. A Telford Premium to Alfred Weeks Szlumper,† M.Inst.C.E., for his paper on "The Signalling of the Waterloo Terminus of the London and South-Western Railway."
7. A Telford Premium to Joseph Harrison, Wh.Sc., Assoc.M.Inst.C.E., for his paper on "Radial Valve-Gears—Analysis of the Motion of the Valve."
8. A Telford Premium to Edmund Gregory Holtham, M.Inst.C.E., for his description of the "Chimpas Aqueduct and Mineral Railway, North-West Mexico."
9. A Telford Premium to Charles Sheibner Du Riche Preller,§ M.A., Ph.D., Assoc.M.Inst.C.E., for his account of the "Zurich Water-Supply, Power and Electric Works."

For Papers read at the Supplemental Meetings of Students.

1. A Miller Prize to Charles Davidson Barker, Stud. Inst.C.E., for his account of the "Methods adopted in Constructing the Glasgow Central Railway—Bridgeton and Tron-gate Contracts."
2. A Miller Prize to David Carnegie,|| Stud.Inst.C.E., for his paper on "The Manufacture and Efficiency of Armour-plates."
3. A Miller Prize to John Wilson Steven, Stud.Inst.C.E., for his paper on "The Introduction of Rubble Blocks into Concrete Structures."
4. A Miller Prize to Francis Gibson Baily, B.A., Stud. Inst.C.E., for his paper entitled "Some Points in the Regulation of Direct-current Motors."
5. A Miller Prize to Arthur Shaw Butterworth, Stud.Inst. C.E., for his paper on "The Disposal of Town Refuse by Burning and the Application of the Heat thereby Generated."

For Papers Read at Local Associations.

1. A Miller Prize to William Robertson Copland, jun., Stud.Inst.C.E. (of Glasgow), for his account of "The Tarapaca Waterworks."
2. A Miller Prize to Philip Morris Pritchard, Stud.Inst. C.E. (of Newcastle-on-Tyne), for his paper on "The Relative Water and Fuel Consumption of English and American Locomotives."

* Has previously received a Watt Medal and a Telford Premium.

† Has previously received a Telford Medal and a Telford Premium.

‡ Has previously received a Miller Scholarship.

§ Has previously received Telford Premiums.

|| Has previously received a Miller Prize.

TESSERÆ.

Water-Colour Art.

THE practice in use by the best artists of the day is as widely different from that which was in use on the invention of our present water-colours as the pictures of the two periods differ in quality of every kind—in colour, richness, depth, variety, effect, &c. The great point in which these two styles differ is that the principle of the earlier mode consisted in using a mixed colour, called neutral tint, and this being made up into a cake of colour, served indiscriminately for the shadows of every kind of subject and season, whether the picture was to represent a land or sea piece, stone or brick buildings, evening or morning, sunshine or storm, summer or a wintry snow-piece. The neutral tint shadows were first laid in, and very frequently (perhaps we should say invariably) served also for distances, clouds and foregrounds, and every kind of object. Cattle, sheep, and the bronzed faces of their attendant shepherds, were most impartially shaded with the same neutral tint, after which a variety of thin washes of colour was thrown over these leaden-coloured shadows, on which they produced so little effect that the designation they received in the older catalogues of the Royal Exhibitions, viz. "water-tinted drawings," or "a water-washed drawing," was the best that could be given to them. These "water-washed drawings" presented an ineffective appearance, although many of them were executed with such an exceeding accuracy of pencilling that, in fact, they became untrue to nature when applied to the distances. In general, the artists of those days trusted to their execution with the black-lead pencil or reed pen for the finish; both very ineffective instruments, especially the former, for producing a natural appearance in painting. The black-lead pencil is very feeble, and the reed pen much too coarse (except in very skilful hands); and both too frequently are used to represent an outline where no outline should be visible, as on the light sides of every kind of object, &c. These remarks on the neutral tint style of painting, sometimes a little varied by using Indian ink or sepia, now fortunately obsolete, or nearly so, are merely given as beacons; for it is too palpable that every season, every kind of object, and every degree of distance must have their peculiar shadows, as in nature they have their own proper colours, to require any arguments against this wrong system, more especially as it is hardly any longer in existence, excepting with a very small number of old practitioners; yet these in the handsomest manner acknowledge the superior effect of the modern style. This style may date its true origin with the invention of the modern water-colours, viz. in 1781. It is to the highly-gifted artist, Thomas Girtin, that we are indebted chiefly for pioneering the way in their proper use, and by his excellent works throwing out of estimation the "water-washed drawings" of his time. These, however, still continued in use for some years after the world had learned, as well from the works of Girtin, Turner and others, that the newly-invented colours were capable of rivalling the hitherto-unrivalled art of painting in oil. Since their first invention they have been considerably improved; their different degrees of permanency, &c., are better known, and chemistry has aided the colour-maker; so that we have not much left to wish for, unless some means could be devised to render fixed a few of the beautiful but fleeting colours.

Early Frescoes in Italy.

By a natural but most unfortunate casualty, the best works of the early painters, being generally in more conspicuous and desirable places than those done in their youth, they were the more liable to perish; the rage for novelty destroying, in each successive generation, the works of the preceding one, in order to substitute its own. It is thus that sometimes two or three frescoes are found painted one over the other in Italy. It was thus that the frescoes of Perugino, of Signorelli, and others, in the Sistine Chapel, and in Stanze of the Vatican, were thrown down to make room for those of Raphael and Michel Angelo. When minds like these are in question, the consolation is obvious—we have got better in exchange; but when we read of similar devastations in favour of the Vasaris, Perino del Vagas, &c., of the decadence, the case is different, and one could weep for very despatch. What a scene of beauty, what a flower-garden of art—how bright and how varied—must Italy have presented at the commencement of the sixteenth century at the death of Raphael! The sacrileges we lament took place, for the most part, after that period. Hundreds of frescoes, not merely of Giotto and those other elders of Christian art, but of Gentile da Fabriano, Pietro della Francesca, Perugino, and their compeers, were still existing, charming the eye, elevating the mind, and warming the heart. Now, few comparatively and fading are the relics of those great and good men! While Dante's voice rings as clear as ever, communing with us as friend with friend, theirs is dying gradually away, fainter and fainter, like the farewell of a spirit. Flaking off the walls, uncared-for and neglected, save in a few rare instances, scarce one of their frescoes will survive the century; and the labours of the

next may not improbably be directed to the recovery and restoration of such as may still slumber beneath the whitewash and the daubs with which the Bronzinos and Zuccheros "et id genus omne" have unconsciously sealed them up for posterity—their best title to our gratitude. But why not begin at once? at all events, in the instances numberless, where merely whitewash interposes between us and them. And what are those "Dii minores," that their works should be respected, when those of the Titans of old time lie concealed behind them? Europe would hail such discoveries as the disinterment of another Pompeii; and a stream of pure refreshment would flow forth for mankind from the walls thus struck by the rod of authority, as of yore from the rock in Horeb.

Modern English Landscape Art.

As with the art of domestic incident, landscape painting is also in strict sympathy with corresponding phases in literature and taste. As the former was contemporary with the modern novel, so the latter has appeared simultaneously with the love of travelling and the love of natural description. These passions (we may justly so call them) are due, no doubt, in part to simple increased opportunity; to recent wealth and peace, and multiplied facilities for journeying. Perhaps the more familiar converseance with nature in her loveliness or her terror, the simple sight of Western Scotland, or Naples, or Monte Rosa, has inspired the wish to transfer to our walls what, in verse or in actual vision, has so charmed our senses: perhaps the poetry of physical science has enlightened and enlarged our sympathies: perhaps the very contrast with the civilisation which enables men to travel readily, deepens their appreciation of the scenes in which civilisation has no part, and even the powers of man seem but a little thing before the majesty of nature. However this may be, the love of landscape has been a glorious gain to modern English art, and gives it its most essentially original character. We no longer see trees and mountains through the imperfect eyes of Claude or Poussin; we do not measure the sunbeams by the standard of Cuyp, or the twilight after the proportions of Rembrandt. Yet this great advance was not made at once. A few artists, of whom Crome and Bonington were perhaps the most gifted, worked in a mixed style, blending the teachings of nature with the traditions of the schools. Others felt the inadequacy of earlier attempts, but have been able to free themselves entirely from a different influence. Something of the art of the stage is united with the genuine art of Stanfield; more with that of Danby and Roberts. Yet the careful pictures of ancient temple and castle, of cathedral and palace, which we owe to the last, are almost without precedent—certainly without rival—in all former centuries. The scenery of Danby, whether that of "perilous seas in fairy lands forlorn," or of the hardly less marvellous equatorial ocean, is a creation beyond the fancy of any earlier painters, as the splendid drawing of Stanfield in rock and sea and lake scenery was beyond their achievement.

The Modulus of Elasticity.

The forces tending to alter the figure or dimensions of substances usually called solid may be thus classified: 1. Extending forces, or such as produce elongation in a body when applied in a direct manner. 2. Compressive forces. 3. Force producing detrusion, or the slipping of one portion of the substance over another. 4. Force producing flexure. 5. Torsion or twisting force. The resistance of bodies to extension was examined by Hooke and Gravesande, and is held to be directly as the area of section of the body, and to increase directly as the amount of elongation produced, at least within certain limits. The measure of this resistance Young termed (not very happily) "modulus of elasticity," expressing the force required to produce unit of elongation (or to double the length) of a prism of the substance under experiment. This quantity may be measured either by the length of a depending prism of the substance which would produce the requisite strain, or more simply by the strain expressed in pounds or tons, which, supposing the elongations to increase without limit as the extending forces, would double the length of the prism under experiment. Thus, in round numbers, a bar of wrought iron an inch square will be extended 1-10,000th part by a pressure of one ton—hence the modulus of elasticity is about 10,000 tons. The elasticity of wrought iron remains perfect to about half the breaking weight, after which the elongations appear to double for each addition of about 1-10th or 1-12th of the breaking weight. Thus, in an experiment by Mr. Edwin Clark a bar of wrought iron, one inch square and ten feet long, extended 8-10,000th of its length for every ton of weight up to 12 tons, from which point the extensions nearly doubled successively for every two tons of load, and the bar was finally torn asunder by 23 tons. The compression of bodies proceeds (like the extension) at first uniformly with the load. Some bodies resist compression more than extension (as cast iron); some the reverse (as wrought iron). Substances give way under compression after different fashions. Hard bodies divide into prisms parallel to the compressing force; slender elastic bodies bend laterally;

soft bodies bulge horizontally; bodies of a medium hardness divide into wedges, and the surfaces slide along the plane of the spontaneous fissure. Detrusion marks more particularly the mode of giving way by the sliding of surfaces in the interior of solids. Though seldom due to force directly applied, it is an important element in most cases of the rupture of semiductile solids.

Mouldings as Evidence of Date.

Although earlier styles were occasionally imitated in completing or altering buildings at a later period, the mouldings of the respective eras were always most faithfully preserved. The assimilating process never extended to the mouldings. To however great an extent the earlier portion of the edifice may have been subsequently copied, these important members were always worked in strict conformity with the ordinary system prevalent at the time of their construction.

Architecture, Sculpture and Painting.

Architecture administering to the first necessities of man is of the earliest origin among the arts. In its development, through a succession of periods, it always shows itself governed by certain general principles, arising out of physical laws and mechanical rules. These have met with so much of the concurrent sanction of ages as now to have become of a fixed nature—principles of conduct to the professor, and deemed so arbitrary that any departure from them is considered a violation of propriety. The code derived from ancient Greek practice is, in fact, considered by the best authorities perfect. Sculpture and painting, on the contrary, though equally governed by principles and laws depending entirely on the representation of natural objects, are susceptible of greater variety—the leading characteristic of the inexhaustible source whence their inspirations are derived—nature. On the manifestations of the truth which they make, and the modes in which this truth is exemplified, much of their success depends. They deny to their votaries the implicit submission to types, which, it is contended, must be yielded by the architect. If these are permitted to control the painter or the sculptor to a similar extent, it must be at the expense of his originality; and if he indulge in any set habits of thought, the conventionalities with which he commences must terminate in the mannerism inseparable from such restricted thinking. Of the three arts, painting has most claim to vitality of purpose. Herein she has the advantage over sculpture of enlisting a wider range and a greater number of imitative truths. Sculpture, with the power of producing positive relief, is wanting in the charm of colour as a means of external realisation. Painting, by the aid of light and shade, simulates this relief so peculiar to sculpture, but superadding colour gives the semblance of superficial truths—the external and characteristic traits of hue or tint which distinguish the special object. The eye, that "mirror of the soul" which the sculptor is constrained to render in an abstract sense, and by means little calculated to compensate for the deficient appliances at his command, the painter expresses by agents that will comply with every regard to variety in structural particular—colour, light and shade, and condition—and can thus portray the inward emotions of the soul with a power and intelligence that make the appeal no less extensive than sure. The appreciation of painting and sculpture, based as they are on the imitation of natural objects, is certain, although it may not always be sound; yet the objects themselves, which it is the purpose of these arts to represent, form so many data whence the relative degrees of the truth of the representation can be estimated. The architect, on the contrary, labours under fewer advantages. He must depend on his public to have either a special organisation or a specially instructed intelligence, to have either his plans or his elevations justly estimated, for the principles he applies being abstract, it is more by the material agency he employs that his art is judged. In proportion as he administers to material wants, he is successful. Our daily experience satisfies us of the defective appreciation of this art. One fact is undeniable—that the great beauty of architecture consists in its fitness. How much is comprehended in that single word. Where any fusion of the principles of architecture, painting and sculpture takes place, the inevitable consequence is a certain loss of the separate integrity of the conditions special to each. For example, sculpture becomes too picturesque when it indulges in imitation beyond the range of its means, or when the imitations can only be partial for the want of the use of colour to make them complete, just as painting becomes too sculptural when the formality peculiar to the plastic art—one of the conditions essential to the expression of repose—gives an impression of permanence of action; and both sculpture and painting may become too architectonic if, when not employed for purposes of mural decoration, they are suggestive of forms and spaces that arise out of architectural intention. Our acquiescence, then, in the manifestations of either of the three arts is just in proportion to the degree in which the principles peculiar to each have been complied with by the artist.

NOTES AND COMMENTS.

THERE is a prejudice against St. Helens on account of its alleged unhealthiness, but many of the inhabitants assert that there are other places which are in a worse condition, and that chemical industries are remarkable for their indirect sanitary advantages. The Local Government Board cannot be indifferent to prejudices, and on Tuesday counsel representing the Board took a very decided action in reference to a Bill that is being promoted by the St. Helens Corporation. It is proposed to extend the boundaries by taking in 690 acres of suburbs, in order to have a wider gathering ground for taxes. The Local Government Board, without any intimation to the authorities, informed the Parliamentary Committee that the scheme for dealing with the sewage of the enlarged district was unsatisfactory, inasmuch as there were no provisions for acquiring land and chemical treatment. The medical officer of the place said there was no need for a special process, as the sewage was thoroughly disinfected by the liquids that came from the chemical manufactories and which passed into the stream. It was also asserted that land adapted for setting-up precipitation works was not obtainable within eight miles of St. Helens. The committee, however, adopted the views of the Local Government Board, and the extension of the borough is not to be carried out until the Board has approved of the arrangements for sewage disposal.

A FATAL catastrophe has been reported from Washington, U.S.A., in the collapse of the building known as FORD'S Opera House. The building has been used of late to house one of the Government Departments. It had the unenviable reputation of being the scene of President LINCOLN'S assassination. It would seem that the front of the structure fell outwards when about three hundred clerks were on the premises, the different floors giving way and falling in a pile on the lowest storey. Since the disaster took place it is reported that many, if not all, employed were aware that the building was in a dangerous condition. It is supposed the excavations carried on by an electric lighting company, for the purpose of introducing the light, hastened a catastrophe that very little would bring about. In excavating for a conduit, the workmen reached the foundations of the columns supporting the old theatre gallery. They found additional columns supporting the upper floors, which were more recent, but all rested on the old supports, which were undermined.

THE Corporation of Richmond have just appealed against a decision of Mr. Justice KEKEWICH. The appeal came before Lords Justices LINDLEY, LOPES and A. L. SMITH, who dismissed the appeal. A person named HATCH, having premises in George Street, Richmond, has recently begun alterations with a view of improving his shop. The Corporation, being desirous to widen the street, served HATCH with a notice, under section 155 of the Public Health Act, to set back the front of his shop ten feet. The section in question empowers the local authority, when any house or building has been taken down, to prescribe the line of frontage to which it may be rebuilt, paying compensation for the land that may be taken for public use under such notice. The Corporation applied for an injunction to restrain HATCH from building beyond the line they had prescribed, to Mr. Justice KEKEWICH, who refused the injunction on the ground that the notice had been served too late. The Corporation appealed, but their lordships dismissed the appeal, because, in their view, HATCH'S premises had not been "taken down" within the meaning of the statute.

A VIGOROUS controversy has been conducted in the columns of the *Sydney Morning Herald* between two members of the Royal Institute of British Architects, namely, Mr. CYRIL BLACKET and Mr. HORBURY HUNT, president of the N.S.W. Institute of Architects. The matter in dispute is in regard of shortcomings in the profession, and to judge from the letters before us Mr. BLACKET has the best of the argument, as it is useless to meet practical complaints by routine platitudes. Mr. BLACKET claims to have been a member of the Royal Institute of British Architects some ten years before Mr. HUNT, and says Mr. HUNT describes as

a pleasant reminiscence his having given "me" his "hand to steady my infant steps while walking with him," a circumstance which Mr. BLACKET does not seem to remember. Mr. BLACKET says:—"Mr. HUNT styles himself a man of letters, and with reason, as, in addition to P.N.S.W.I.A., this English affiliation will enable him to put five more, F.R.I.B.A., and apparently he 'hankers' after a few more, as he has chosen promiscuously R.B.P.P.W.—truly a good array, sixteen letters; but it is well to bear in mind that the public have been surfeited with such honours. I have at this moment a letter before me from a builder with the potent letters F.R.I.B.A. after his name, apparently because his connection with the Builders and Contractors' Association afforded his vanity no such opportunity for display."

A LETTER also appears in connection with this controversy in the same paper from Mr. W. NICHOLLS, as follows:—Having seen correspondence in your columns between two architects as to the reasons why a number of buildings are erected without their aid, I think the public should be a little further enlightened. Now, it is well known to every builder in Sydney, and I will venture to say every architect, that a system of tipping has been going on for years between some builders and some architects, and no steps have been taken to put a stop to it. There are, I will admit, a number of architects in Sydney who are upright men, and it is a pleasure to work under them; there are others who will and do ruin the builder, unless he is prepared to hand over black mail. Mr. HUNT speaks of what they are going to do as they get stronger; but every honest builder would like to see a start made and a stop put to this kind of trading. It is no wonder that architects are not better employed, because builders are getting tired of this kind of thing, and in very many instances have managed to influence persons building to do without an architect altogether. The remedy for this kind of thing is, in my opinion, to take away a great deal of the absurd power that the architects claim to have over the builder, and which no proper architect ever requires or uses. It is only of use to the incompetent and blackmailers.

THERE is a time in the life of every Frenchman who studies literature when it is believed that the representative poet of the nineteenth century was ALFRED DE MUSSET. Some adhere to that opinion during their lives, others are less faithful; but if they vary in their allegiance, they are always ready to admit the power of DE MUSSET'S spell. Neither HUGO nor LAMARTINE gained the hold on the French mind which is still possessed by his books. It is remarkable, however, that with all the admiration of him which exists in France, there is no statue of him to be seen in Paris. Men who were born since he died, thirty-three years ago, have been awarded public memorials in bronze or marble, while his name is only to be read on printed pages. An effort was lately made to atone for the neglect, and several of the most prominent of living writers in France formed themselves into a committee and invited subscriptions from their countrymen. The money did not come in. The project must have collapsed if M. OSIRIS, the Greek merchant, had not once more appeared as the champion of French celebrities against neglect and ingratitude. With the same sort of generosity he showed when he purchased M. FRÉMIET'S statue of JOAN OF ARC in order that it might be set up in Nancy, on the borders of Alsace, he has now undertaken to bear all the cost of the memorial to DE MUSSET. This act is most creditable to M. OSIRIS, but when the work of MM. MERCIÉ and FALGUIÈRE is executed it will be enduring evidence of the odd manner of bestowing fame which is found in France.

WE hear that the Ninth Annual Exhibition of inlaying, woodcarving, carpentry, repoussé metal-work, iron, embossed and cut leather, pottery, baskets, rugs, embroidery, lace, hand-spun linen, smocking, bookbinding, wool, home-spuns, &c., will be opened at the Royal Albert Hall on the 22nd inst. Among other matters it has been arranged that a potter will throw vases and pots on the wheel and afterwards decorate them in sgraffiato and barbotine. There will also be demonstrations of Swedish weaving, spinning, inlaying, woodcarving, leather embossing, basket making, &c. The exhibition will close on the 26th inst.

The Architect, June 16th 1893.

THE HALL OF THE COTTAGE, WALTON HEATH.

AN exterior view and plan of this building—Mr. B. VAUGHAN JOHNSON, M.A., architect—has already been published in *The Architect*.

WURTZBURG.

MARQUIS OF GRANBY PUBLIC-HOUSE, SHOPS AND RESIDENTIAL SUITES AND STABLING.

THE block of buildings, as illustrated, covers an area of about 7,000 superficial feet, and the accompanying plan will best show the general arrangements. The stable plan has been very carefully considered, and by means of two entrances (in Down Street and Brick Street) from different levels three floors have been utilised, without necessitating any steep gradients for the horses. Haylofts, harness-rooms and accommodation for the men have been arranged over the stables, which are well ventilated and lighted throughout. The Marquis of Granby public-house covers the exact site of the old house, and the bar fittings and other joiner's work are executed in walnut, panelled and enriched, of a handsome character. The shops in Down Street are constructed to let with basements, and the upper floors contain bachelors' suites. The elevations are carried out in red brick, with stone dressings and granite pilasters to ground floor. Messrs. MARTIN & PURCHASE, of 11 Queen Victoria Street, E.C., were the architects for the stabling, shops, chambers, &c.; and Messrs. BOEHMER & GIBBS, of 11 Spring Gardens, S.W., superintended the erection of the Marquis of Granby public-house. Mr. FRANK KIRK was the contractor for the whole of the works.

WASHINGTON.

IN the *New York World* is an article from the pen of Mr. M. G. Van Rensselaer, from which the following is abstracted:—

It is trite to say that Washington is a beautiful city at this time of the year. But it is not trite to emphasise the part that the season plays in producing its beauty. People who have not seen Washington at other seasons, or who have not inquired curiously into the source of the impression it makes in spring hardly realise how peculiar its beauty is. It is unlike the beauty of any other town I remember either in this country or in Europe.

Travelling through Europe we come now upon a city whose charm is wholly architectural; again upon one, like Edinburgh, whose charm is almost wholly that of site and outlook, and again upon one like Florence, where we can hardly decide whether loveliness of site or architectural dignity plays the greater part in determining its attractiveness. But Washington does not fall into either of these categories.

It possesses, of course, some very fine constructions, and among them two which are as beautiful as any in the world—the dome of the Capitol and the Washington Monument. And it has the advantage of lying beside a wide river with hilly and picturesquely wooded banks. But its fine buildings are scattered and are mixed up with so many which are far from fine, and some of its principal streets are so poor, shabby and heterogeneous that, taken as a whole, the city is by no means architecturally impressive. And, apart from the vicinity of the river its site is devoid of natural advantages. It has neither the hilly streets which give picturesqueness to Edinburgh nor that outlook upon near lofty mountains which makes the beauty of Salzburg; nor does the river run through it and form the chief feature of the actual urban panorama, as is the case in the splendidly beautiful city of Prague.

The beauty of Washington is the beauty of art, not of nature, and yet it is not the beauty of architectural art. It is a beauty which has sprung from the hand of the landscape architect—L'Enfant, the engineer who planned it, and Mr. Olmsted and the other artists in his branch, who have planted and decorated it, have been the creators of its charm to a degree which cannot at all be realised by those who have never seen it.

The White House, for instance, is a dignified, well-proportioned, well-featured building; but deprived of its grounds, standing in a naked square or closely pressed upon by other structures, one would hardly remember it as among the most delightful residences he had ever seen. The Capitol is impressive by its size, and even apart from its beautiful dome, has considerable excellence. But without the wide marble terraces, which Mr. Olmsted planned, and without the grounds which he laid out, it would be shorn of three-fourths of its effectiveness

from any near point of view. And if the scores of squares and circles and other open spots and strips of land, which the intelligent planning of the streets has kept free from buildings, were less charmingly planted, and if every street almost from end to end of the city were not set with a double row of flourishing trees, no one would go home from Washington even in spring with a strong impression of its beauty. Abstract the work of the landscape gardener, and of the engineer who prepared for him, and we should have but a commonplace town, distinguished chiefly by two very admirable constructions—the dome and the monument.

There is a lesson in these facts for all planners of new towns in the West and for all guardians of old towns in the East. The most prosaically planned and crowded of our towns might be vastly improved if the landscape gardener's services were generously called into play. And the planning of Washington is so sensible as well as rich in possibilities of beautiful planting, that it might well be imitated on any flat side. One cannot expect modern planners to reproduce that convenient casualness of street line which renders Mediaeval towns delightful to the eye, but a mere gridiron pattern is not the only alternative. The basis of the street planning in Washington is a gridiron of straight streets intersecting each other at right angles, but the simple and useful device of cutting wide avenues diagonally through this groundwork has meant all the difference between monotonous ugliness and varied beauty.

Nevertheless, I do not wish to underestimate the value to Washington of its better buildings, and especially of the two which I have already twice named. Even a pretty good dome is apt to be a priceless possession to a city, as the aspect of Boston proves; and a really fine dome is a better possession than any other single thing can be, and the Capitol dome is very fine indeed—one of the three or four most beautiful large domes in the world. I know that it is not aesthetically virtuous in construction. I know that it is woven of iron, not built of solid stone or brick, as are the famous domes of the elder world. This fact detracts from its purely architectural interest, but it does not detract from its ocular charm. When Mr. Walter designed its lines he designed a shape of beauty which needs no justification, no explanation—a shape which is satisfying and impressive when seen near at hand, commandingly, enchantingly lovely when seen in the far distance; and, fortunately, one does not see it in the far distance—perpetually, persistently, and over foregrounds of the most wonderful variety. The longer one stays in Washington the more constantly one is on the watch for it, and the more enthusiastically one appreciates it, however and wherever it meets the eye.

But even more remarkable than the dome is the monument, which also and to an even greater degree dominates the city and impresses itself upon the eye and mind of the visitor. There are other domes in the world; there is no other monument of this sort. We compare the chief feature of the Capitol with a few other great monuments; we cannot compare this vast single self-sufficient shaft with anything else, or even contrast it with anything else. It is a unique thing, and I am fast getting to believe that it is the most beautiful thing in the world. Of course one is often tempted to such a decision in face of any remarkable work of art; but I believe that in this case absence and the sight of other marvels will not greatly weaken my present impression.

It is, or was, somewhat the fashion among would-be æsthetic people to sneer at the Washington Monument, to say that it is not a work of art at all, but merely a proof of mechanical ingenuity; to declare that it is remarkable only because it is big, and that to admire mere bigness is a sign of æsthetic barbarism. But people who talk like this have never looked at the monument or they have had no eyes wherewith to see it. Truly it is big; it is 555 feet in height and, I think, not any other structure in the world is so tall, except the Eiffel tower, which no one would affirm to be a remarkable work of art. And truly its size plays a very large part in determining its magnificent beauty. But no one who really comprehends architecture will be disturbed by this statement. Size is always a very potent factor in architectural beauty of the grander kinds—is æsthetically important here as it is not in other branches of art. A pyramid, a cathedral, a palace, a castle, implies grandeur of effect, and this we cannot have in architecture without grandeur of scale. It is the same with architecture as with trees, for instance. A little oak tree may, in one sense, be as beautiful as the biggest. But the bigger an oak tree is, if its proportions are fine, the more dignity and impressiveness it has, the more forcibly it speaks to the imagination, the more remarkable and potent is its beauty.

Moreover, the simpler a work of architecture is the more distinctly size contributes to its effect. An elaborate cathedral greatly reduced in scale might still be very beautiful, but not so a simple pyramid. An obelisk is as simple as a pyramid, and therefore the bigger it is, provided grace of outline is preserved, the more impressive it will be. When the Washington Monument was built to a height of 555 feet it was made five times more beautiful than had it been built, with the same lines to a

height of 155 feet. Indeed, the increase in beauty was proportionately much greater than this: it was incalculable in degree. There can be no real comparison between the impressiveness of those Egyptian obelisks which we are accustomed to think large and the impressiveness of this vast snowy giant on the banks of the Potomac. Of course an Egyptian obelisk consists of a single stone, and this one of a great multitude of small stones; but this fact does not impair its beauty, as would be the case were it as small as they. It is so vast that no one could be foolish enough to imagine it a monolith; therefore it does not deceive the imagination, as do, for instance, the pseudo-Greek columns of the Madeleine in Paris, which ought to have been monolithic, and are not.

The monument was forty years in building, and the design was greatly simplified when, after a long period of inaction, work was begun upon it for the second time in 1876. It is now a perfectly simple shaft, rising directly from a flat platform. The original idea was to have the shaft rise to a height of 600 feet from the centre of a great circular hall 100 feet in height and 250 feet in diameter, and surrounded by lofty colonnades.

No guide-book tells me who conceived the original scheme, or who was responsible for its alteration, and what guide-books do not tell no one else in Washington seems to know. But the second person concerned in the matter has surely given us a finer thing than his predecessor imagined. The proportions of the obelisk are now so perfect that one cannot help believing that 50 feet of additional height would have injured them without increasing majesty of effect, and the simplicity of the baseless shaft is infinitely preferable to one's mental picture of the original conception. An obelisk needs no base—its character, its distinctiveness, its reason for being resides in its bold, naked independence. This the Egyptians knew, although their knowledge has not been shared by most of the moderns who have re-erected Egyptian obelisks on occidental sites. And the bigger an obelisk is the less it needs a base—the more distinctly a base would detract from that expression of soaring self-sufficiency which makes its individuality, its singular impressiveness. The Washington Monument would be as greatly injured by an elaborate supporting structure as by a statue on its apex. The present platform should be encircled by balustrades and terraces at a distance from the shaft, but the shaft itself should remain for ever just as it is.

To stand beneath it and gaze upward along its limitless snowy sides means an impression of a peculiar sort which no other work of men's hands can give; and to see it from a distance means a vision of beauty, force and majesty, which makes us affirm that simplicity is indeed a more potent kind of beauty than the richest elaboration. Smaller, it would be merely handsomer; now it is magnificent. With less beautifully graceful proportions it would be merely big; now it is powerful beyond words. And its size and shape are incalculably enhanced by its colour. Such a shaft built of dark stone would be very imposing, but it might not be very beautiful. White is the only colour which could mean perfect beauty in a monument of this size; and white of just this quality—white which is not cold and hard and glittering, but soft and tender like the colour of new-fallen, uncrusted snow. Whether one sees it against a bright blue sky or against clouds almost the same as itself in tone, or against heavy curtains of leaden grey, its colour is always exactly right, making a splendid contrast to its background or a delightful harmony with it.

When one consents to look away from the monument and the dome and the ever present verdure of Washington to its domestic and governmental architecture, one's feelings are less simple. Now one admires, now one energetically protests, and occasionally one bitterly grieves.

As a whole the domestic architecture of the newer parts of the town is not unlike that of upper New York, on the west side. It is much less fantastic, unreasonable and heterogeneous than the domestic architecture of Chicago; yet very queer specimens of aberrant art frequently present themselves. As I had not visited the city before for a space of some ten years, I could judge pretty well how violently enterprising American architecture had become during this period. About ten years ago Mr. Richardson had recently completed four or five large residences, and they were pointed out to every stranger as marvels of originality—even of eccentricity. Both those who admired them and those who did not thought them extremely bold, extremely unconventional. To-day these houses are seldom pointed out, and when they are it is simply to say that the great Richardson built them. And to-day they look quiet, reserved, almost conventional, in comparison with many of the things which the past ten years have produced.

The "Morning Post" says:—A remarkable discovery has been made at Carrog, near Llangollen. While a number of workmen were carting stones from the bed of the river Dee they discovered the remains of an ancient church, which was washed down by a heavy flood three hundred years ago.

STAINED-GLASS.*

"TRUTH," someone has said, "never can be confirmed enough," and nowhere does this statement apply with greater force than in matters of art.

When a truth has once found acceptance the wonder is that there should be any temptation to depart from it, yet history shows that whenever art has flourished or declined its rise or fall has been the result of its adherence to, or departure from, the laws which govern it.

All the arts cluster around that of architecture as the source from which they derived their being. "Men built houses before carving them, and carved before painting them," says Viollet-le-Duc. Sculpture and painting are, therefore, but helpmeets of architecture, sustaining independent and harmonious relations each to each when justly balanced. We have so long lost sight of this truth and are so accustomed to regard sculpture and painting as independent arts, each sufficient unto itself, that it requires an effort to realise that in the beginning both arts were evolved as accessories to architecture, and that there was no sculpture nor painting except as decorative adjuncts.

The evolution of the stained-glass window may be traced step by step to this fountain-head of all the arts, for the stained window is only an offshoot of the earlier art of painting, which had at first only a decorative function. Painting at the very outset was of the nature of symbolic representation, and was one of the earliest arts in which the creative faculty of primitive man was brought into play. It was this symbolic art which the early Christians appropriated to their use, for various reasons. First, because of its suggestiveness and power of appealing to the imagination of the illiterate, who were to be instructed in the faith; second, because, while having a peculiar significance to the initiated, it guarded the mysteries of the brotherhood from hostile scrutiny; also because there was at that time a dislike of direct representation of Deity. These were the practical ends which religious symbolism was designed to serve. But, as the Church grew in wealth and power, it began to feel that one of the ways of glorifying God was in beautifying His temple; so beauty and utility conspired and caused to exist some of the sublimest creations the human mind could conceive. By degrees this symbolism grew into a more literal portrayal of Church history and tradition, so that the walls of Roman and Byzantine interiors were decorated with frescoes representing scriptural scenes, the apostles, saints and martyrs. These interiors, owing to the small window openings, were lighted for the sacred service by artificial means, tapestries often being hung over the windows. But when stained-glass made its appearance in the twelfth century, probably from some Oriental source, churchmen were quick to transfer their decorations from the opaque and poorly-lighted walls to the translucent surfaces of the windows.

In effecting this change, however, they did not lose sight of the fact that their window ornament, as well as their wall-decoration, was to be kept subordinate to and in harmony with the architectural surrounding. All antique work is distinguished by this strict adherence to decorative principles, which does not permit either sculptured or painted ornament to transcend certain limits.

Stained-glass design, particularly of the earlier Romanesque period, had generally the effect of tapestry. The figure and all natural forms, when used as *motifs*, were severely conventionalised and in one plane; consequently without perspective or chiaroscuro. We may be able to determine exactly what constitutes the essentials of good stained-glass, and what its proper treatment should be, by noting the properties of the antique art when at its best, and if we can rightly understand the cause of the decline of the stained window in the sixteenth century, we may save from a similar fate that of the nineteenth century.

The advent of the Gothic style, with its reduced wall-spaces and larger window-openings, was the opportunity of the glass-worker of the twelfth century. To fill these vast openings with some material which should at once exclude the weather and admit the light was his task, and as the antique glass could be made only in pieces of limited size, it became necessary to build up a mosaic of numerous pieces, joined by strips of lead, in order to make panes of area equal to the windows.

Throughout the Mediæval period this mosaic method was strictly adhered to. The artists recognised the limitations laid upon them by the nature of their material, their designs being mostly confined to the arrangement of pieces of coloured glass in geometrical and other fanciful patterns. They made no effort to conceal the unavoidable lead lines, but rather forced these to perform certain functions in the artistic as well as mechanical economy of their windows. But they refrained from attempting to make pictures out of them, and during this

* A paper read before the Minnesota Chapter American Institute of Architects by Mr. W. A. Hazel, and published in the *Inland Architect*, Chicago.

period of more than 300 years there is no instance of an attempt at realistic portraiture. The antique workman was content to get the most out of his material in the way of gorgeous colouring. Design was of secondary importance and restricted in range.

The peculiar virtues of Mediæval windows were due to the quality of the glass they had at hand. In its manufacture their knowledge as well as facilities were extremely meagre, and their small knowledge of chemistry gave them a very limited palette. But this handicap was itself the cause of much of the beauty of their raw material. Being obliged to make it in small pieces, they were necessarily forced to retain the mosaic process; this was well for the art. Then, too, their glass was heavy, of unequal thickness, full of bubbles, coarse-grained and of uneven texture. All these mechanical defects made the antique glass the ideal material for mosaic windows; they made it scintillating and luminous, full of deep, mysterious colourings, making thinness and monotony impossible. Such was the best estate of the glorious old Mediæval window, "casting a dim religious light," of which the poet sings.

Now, what was the cause of the decline? With the fifteenth century came the Renaissance, and with it the new form of art—oil-painting. Just at this juncture certain mechanical improvements were made in the fabrication of glass. Vitrifiable or enamel colours for glass-painting were also discovered, and a yellow stain made from silver. These conspired to overthrow the old art of mosaic. In the first place the improved method of glass manufacture produced a more mechanically perfect material. It gave larger panes, uniform in thickness, smoother in texture, and more homogeneous—i.e. more compact, without the air-bubbles which gave the gem-like effect. These changes alone meant loss of vitality in the material itself. It became thin, weak and monotonous. Then the invention of enamel colours led the artist to attempt the imitation of the effects of oil-painting. This was particularly harmful. The craftsman threw away his fine old glass, and took the new smooth material upon which he could paint, loading it with the opaque enamel and still further deadening the glass which had already lost its vitality.

Of course it proved impossible to make a realistic picture in glass. The hard lead lines bounding the different planes of the perspective destroyed all pictorial illusion, so, like the dog in the fable who saw his reflection in the water, the old artist dropped a choice morsel to seize a shadow, and—lost all. For three hundred years he had followed Truth. When he forsook her his art disappeared.

From the beginning of the sixteenth century to the middle of the nineteenth is a long leap, but during the interim the art left no record worth noting. There was the so-called revival in the eighteenth century, during which some restorations and repairs of old windows were made, and some new ones in imitation of the old. But it was not a revival in any true sense. A real revival is a reversion to principles and not a mere resurrection of old forms without the spirit which formerly animated them. No such revival occurred until the last quarter of the present century, when American artists inaugurated a new era in the history of stained-glass, and placed the art upon a plane it had never before occupied. Returning to the antique mosaic method, American artists have made glass equal in every respect to that of the olden time, with the added virtue of almost limitless range of colour, thereby furnishing an illustration of old principles taking root in new soil, springing into vigorous life and bearing fruit before unknown. We not only abandoned the use of paint, which deadened the lustre of the glass, but we reaffirmed the old truth—that stained-glass is an accessory art, an architectural adjunct, designed to enrich that of which it is but an integral part, the architectural unit.

Mr. Van Brunt, speaking of the effect upon architecture of our geographical isolation, says:—"We occupy a new country, having no inheritance of ruins, and no embarrassment of tradition; in matters of architecture we are absolutely free from historical prejudice," or—he might have added—historical example. This condition however was suddenly changed in 1876. In that year the Centennial Exhibition brought great numbers of European artists to America, and their work supplied the lack of example, not only with regard to architecture, but all the decorative arts as well. Our manufactures were given a needed stimulus, and then began that wave of æstheticism which swept over the country, and has not yet subsided.

In the centennial year two great men and two great opportunities met and shook hands. Henry Hodgson Richardson and John La Farge were the men. The building of Trinity Church and its decoration were the opportunities.

But for Mr. Richardson Trinity Church would have had no existence, and had Trinity Church not been built Mr. La Farge, one of the foremost living colourists, would not have been called upon to decorate it at a time when the air was full of these new influences, and he might have remained to the end of his days a painter of easel pictures only.

But Mr. Richardson having built the church and Mr. La

Farge having undertaken its decoration, it became evident that the "priceless glass" in vogue in Europe would prove inadequate for such an interior. So, spurred on by necessity, Mr. La Farge began making investigations and experiments in coloured glass, with results which revolutionised the process of glassmaking. Previous to this time we had gone so rapidly to the bad in the production of machine-made stuffs that we had about reached the point where the workman "pressed the button and the machine did the rest."

Now came the transformation. Manual dexterity, backed by intelligence, was substituted for senseless machinery. Improvement in the artistic quality of glass was at once manifest. The worthless stuff which had supplanted the antique material in its turn gave place to a new fabric having the same qualities possessed by the glass of the Mediæval craftsman. Material which had been previously discarded as imperfect and worthless by reason of accidents and miscalculations was found to have just the variety of tone and colour most desirable, so that the worst failure often included the greatest success. In the new we had rediscovered the old, and in opalescent glass contributed a purely American product to art.

Now the question which concerns us as artists, whether architects or glassworkers, is this. After having seen this rejuvenated art occupy the high place which La Farge gave it—ior he alone has held steadfastly to the fundamental decorative principle—shall we tempt the fate which blighted the art in the sixteenth century? We stand to-day as to the modern art in the same relation as did the fifteenth-century artist to the antique. The next step may be forward or backward; which shall it be?

There is no such thing as remaining stationary; that is contrary to the universal law; there must either be progress or retrogression, growth or decay.

Art can never realise absolute perfection, but it is on the road to it so long as it holds to rock-bed principles. The art of the ancient Greeks is proof that the highest excellence is attainable and maintainable only by the observance of this law. Without desiring to take a pessimistic view of the situation, I do not hesitate to say that, for stained-glass in particular and the decorative arts in general, I see "breakers ahead." The tendency to overstep the prescribed bounds of accessory arts is noticeable in some of our most prominent work, and the cause is not far to seek.

We produce our art, as we do everything else, on a large scale. Our art establishments are huge institutions. It is necessary to their maintenance that the public should buy. If it will not buy art we must sell what it wants, and if it doesn't see what it wants, all it has to do is to ask for it. And we have scriptural warrant that "those who ask shall receive."

We are inventive and admire a "clever" thing more than we do an artistic thing. Consequently our bump of inventiveness is abnormally developed. The man who produces the newest thing, or the biggest thing, or the most ingenious thing, is the artist *par excellence*—for the multitude. The multitude has the money, and must be gratified, if the artist has to violate every principle upon which his art is based. We have the national fault of letting our cleverness carry us beyond legitimate bounds, partly in mere exuberance of cleverness, partly for mere display, or a desire to win vulgar applause by being thought more clever than our fellows. It requires considerable moral stamina to stop short when the artistic conscience says "thus far and no further."

The greatest sinners in this respect are those who ought to and do know better, but cannot withstand the craving for popular favour. To be an artist and hold with one's conscience one must be pecuniarily independent and indifferent to popularity, or he is liable to go begging, both for dollars and fame. As an illustration of this tendency one instance will suffice:—One of the most ambitious, recent stained-glass windows, and one which is often cited as a "splendid work of art," was made by a well-known firm of reputed artists. In this window is reproduced Doré's picture, *Christ leaving the Praetorium*, in which, in my opinion, every law which should govern true decorative work is transgressed, not through ignorance, but knowingly and wilfully, for the sake of dollars and the applause of the multitude.

I am aware that the criticism I shall make involves a point debated among artists respecting the limit to which naturalistic treatment in glass may be successfully carried. It seems to me that the question should be, not what may or may not be successfully done, but what ought or ought not to be done, whether successfully or not. In stained-glass windows pictures should be rigidly excluded, because upon principle they are wrong. The aim of a picture is to create an illusion by a simulation of nature. In decorative work any treatment which admits a doubt as to the actuality of the thing decorated is wrong. A picture is an entity. Its values are intact within its own extent, and it is unrelated to anything beyond. But designs which are suitable for wall-decorations or windows should make the surfaces of both self-evident. A painting which transmutes a solid wall into thin air is wrong in prin-

ciple; its proper function is to beautify the wall, but not to make it a less substantial fact. The plane of the window is a continuation of the wall plane; therefore to make a picture out of a window is wrong, because it resolves the window into other planes than that of the wall in which it lies, and for the stronger reason that it sets itself up as an independent entity when it should be but an integral part of an architectural unit. Consequently the transference of a large canvas painting to a window, as in the *Christ leaving the Prætorium*, banishes the window plane and leaves in its place a vista of palaces and multitudes and all the illusion of sky and air which perspective and chiaroscuro can accomplish. This is as obviously wrong as the *New Jerusalem* in Trinity Church and the Ames memorial at North Eaton are right. The last conform to decorative principles; the first contravenes them.

From this it may be seen that the signs are not lacking which tell that the newly-recovered art is yielding to hurtful tendencies; is starting or about to start down-hill again. It is the architects to whom we must look to check it by their influence. The public must be educated to the point of ability to know good from bad, or there is no future for architecture or its dependent arts. People should be taught that there is an absolute right and wrong in the realm of æsthetics; they must learn that art is not governed by caprice or arbitrary formulæ, but by well-known laws, easily ascertained if one will but take the trouble.

In the hurry and impatience of this electric age we cannot hope, perhaps, ever to command the leisure of the ancient Greeks for the cultivation of the arts; neither will we come under such a dominating influence as were the Florentines of the fifteenth century, when "every new structure became a school of the eye and the taste." But it is not impossible for us to reach that condition when, by education, the judgment of the people will have become so good that artists will not hesitate to appeal to it. The assurance that merit can safely appeal to such a tribunal will stimulate each to his best endeavour. The artist and the public will react each upon the other; the artist educating the public by constantly keeping before it the highest ideals of his inspiration; he, in his turn, kept to the true path by the exactions of an educated and fastidious public, quick to recognise the powers exerted in its behalf, and to commend and reward if also to criticise; each capable of appealing or being appealed to, confident of intelligent and sympathetic appreciation.

HYDRAULIC LIFTS.

(Concluded from page 377.)

IN one form of suspended low-pressure lift, shown by diagram, the cylinder is stood vertically, and the water is introduced above and below the piston, by which means nearly an equal power is exerted throughout the entire stroke; as the pressure due to the height of water above the piston, and the sucking action of the column of water beneath the piston combined, would be the same in any part of the stroke if it were not for the small area of the piston rod, and this slight loss of power, as the piston descends, is generally more than compensated for by the weight of the ropes suspending the cage, passing over the top sheave from the cage to the opposite side; if it were necessary by apportioning the size of the rod and the weight of the ropes, an exactly equal power could be obtained throughout the whole travel of the lift. This is a very good arrangement, and was introduced into use in this country some years since by the American Elevator Company, but, strange to say, this exact form was patented in this country by Harriott and Strode in 1802; the specification is not now in print, but it can be seen at the Patent Office Library. It is most carefully and accurately drawn, and describes this method of using a vertical cylinder. The author merely mentions this as showing how curiously before its time this invention was.

An ingenious arrangement also was illustrated for balancing the weight of the ram and cage of a direct-acting lift, and at the same time equalising the power throughout the travel of the lift and thus reduce the quantity of pressure water used. The displacement ram is weighted to nearly counterbalance the weight of the lift ram and cage as in the Ellington balance, but the actuating ram acts on the displacement ram through chains or ropes which coil on to cam-shaped barrels or fuses, so that the downward pull on the displacement ram increases as it descends, thus increasing the pressure as the lift ram ascends, obviating any loss of power by protrusion. The balance was patented by Mr. Archer, and is manufactured by Messrs. Richardson & Co., Limited, and is an example showing the endeavour lift manufacturers are making to reduce the quantity of water used by their lifts to a minimum.

Mr. Carey directed attention to a new system of hydraulic lifts and cranes, by which the quantity of water used is automatically approximated to the load raised. He is quite aware that multiple power machines have been made for a great number of years, that is, multiplying cylinders or jiggers, and

also direct-acting lifts with more than one ram, a light load being raised by admitting water to one ram, a heavier load by admitting it to two, and so on. In some instances a ram and piston is used when the pressure water is admitted to both sides of the piston, the annular space round the ram is in equilibrium, and the area of the ram only is effective when the pressure-water is admitted to the back of the piston, and when the water from the annular space round the ram is open to exhaust the whole area of the piston is used and the maximum load may be lifted. In other arrangements there are two rams, the smaller one working inside the larger, the bottom of the large ram being open. When a light load is to be raised the large ram is held back by powerful claws or clips attached to the cylinder; when heavy loads are to be raised the large ram is released and the two move as one. In this arrangement the combined areas of the two rams are not used, but the area of the large ram has to be sufficient of itself to raise the maximum load. All these methods, however, are more or less clumsy, and must take time to alter from one power to another. Therefore, on account of the time and trouble involved, the alteration is only made when a great number of light or heavy loads have to be raised in succession. The arrangement that looks most promising at first sight is that in which the power is increased by simply pulling the hand rope further on, the water being admitted to two rams, or the exhaust made from before the piston as before described. But there are difficulties in this; for instance, if a heavy load has been raised and the lift stopped, the rope only having been moved to the point at which it will stop when the heavy load is in the cage, when the load or part of the load is taken out the lift starts on again until the rope is moved still further. This, of course, is a serious fault; it may perhaps be provided against, but the fact of leaving the attendant the option whether he will go on to the first or second power is not satisfactory, as, in order to save trouble, he will generally elect to go on to the second or largest power, although the machine was intended to save water and not trouble. Again, with this arrangement there cannot well be more than two powers, whereas, to be a really economical machine, there should at least be three powers or grades, if not four or even more, and the discretion as to which grade should be used should not be left to the person working the lift or crane, but should be automatically selected.

Successful attempts have been made to prevent the valve from opening to the second power or grade until a certain pressure has been obtained in the cylinder, indicating that the maximum lifting power of the first grade was nearly reached. The movement of the controlling rope or lever should be always the same, and the speed should be under control as well as the stopping and starting in either direction. All these conditions, the author claims, are met and successfully carried out in his system, which he will now explain.

A lift which has now been working for some months, showing a great saving over the usual form in the water used, is fitted with two jiggers. One is practically the ordinary description, but the other is a four-power machine. They are both constructed alike, so far as the multiplying power goes—that is to say, they both multiply four to one, and are therefore both the same stroke. The ropes suspending the cage can be readily shifted from one machine to the other. One machine was first run for some time and then the other, and the water used by the machines compared, and the actual saving shown in such a way that it is impossible to question the saving effected:—

ORDINARY JIGGER.

The multiple power jigger has one ram $3\frac{1}{2}$ diameter, pressed downwards by the water to raise the cage; this is assisted by weights added to cross-heads which are sufficient without assistance from the pressure water to raise the cage with attendant and one passenger. There are three small rams fixed at the bottom which oppose the power of the large ram. The centre one of the three is 2-inch diameter, and works through a stuffing-box into the interior of the large ram; the other two outside rams are $1\frac{1}{2}$ diameter each, and work into the two sides or tension rods, which are made of tubes to form cylinders for them; the two rams always act together as one. The action is as follows:—For the first or lighter power the power-setting valve is so placed that the exhaust is made from all the cylinders or rams; the load is raised by the weight on cross-head alone. For the second power the pressure water is

admitted into all the cylinders, the large ram is then opposed by the three small rams, but as the area of the large ram exceeds that of the three small ones increased lifting power is obtained. For the third power, the centre ram is opened to exhaust, the large ram then only has the two outside rams to oppose it. The fourth power has all the three bottom rams open to exhaust, when the full power of the large ram, assisted by the weights, can be used to raise the maximum load. To lower the empty cage, pressure water is admitted to the centre ram, all the others being open to exhaust; the weight of the cross-head, &c., is raised by this means; if a heavy load is in the cage no pressure water need be admitted, the weight in the cage raising the extra balance weight.

The principle of working the valves is very simple, and the details are not complicated, there being two valves—the starting valve and the distributing or power-setting valve. When it is wished to start the lift up, the controlling or starting rope is pulled down to the limit of its movement, the starting valve being thus opened in the usual way. At the same time, the pressure water is admitted to the back of a small piston, which actuates the distributing valve which commences to travel forward. If there is a light load in the cage, and the lift commences to move, the movement actuates a pawl, which is immediately dropped, and the further movement of the valve is arrested, the lift making the ascent on the first or smallest power. If the first power or grade is not sufficient to raise the load, the distributing valve continues to move from power to power until the right power is found, when the lift commencing to move the pawl drops and arrests the further movement of the valve. There are various ways in which the pawl can be actuated. The one now in use is a small ordinary governor driven by a small wire rope attached to the moving head of the jigger. When the lift commences to move at the required speed, the balls fly out and lower the pawl; when the lift is stopped the pawl is raised again by the weight of the balls, the distributing valve always returning to its first or normal position directly the lift is stopped. The stopping of the lift, either on its ascent or descent, depends upon the starting valve in the usual manner, and has nothing whatever to do with the position of the distributing or power-setting valve; and therefore the ordinary automatic stops on the starting rope, tapped by the movement of the cage, act as usual at the top and bottom of the travel to prevent overrunning. Instead of the governor a small wheel was caused to revolve when the lift started, the pawl resting on the top of the wheel by a vertical pendulum stop, which was moved to one side or the other when the wheel revolved, and thus dropped the pawl to arrest the further movement of the power-setting valve. This was found very efficient in practice; but the neatest and most reliable way of actuating the pawl is by a small loose-fitting piston, causing the pawl to drop when the water commences to flow, and raising it again when it ceases flowing. It would be tedious to describe in detail the various means of arresting the further movement of the power-setting valve, when the lift commences to move; but by doing this the great advantage is obtained that, however much the actual friction of the machine may vary, when the grade or power is reached that will do the work, then, and not until then, is the valve stopped from going on to the further powers. Therefore, when the jigger is repacked, and there is probably much more friction than there will be a few days afterwards when the packing has become free and easy, the working of the machine is not interfered with, although for a short time rather more water may be used to overcome the extra friction. It will at once be seen that this is a much more economical arrangement than any that could be devised dependent upon the varying pressures created by the load in the cylinder, as in that case a larger margin or lap must be allowed to each power. That is to say, a large power must be started before arriving at the full power of the grade next below. If made to act too closely, constant readjustment would be required to suit the varying friction of the machine. With the arrangement described, each grade will work up to within a few pounds of its maximum power before the next grade is started, hence the great economy of water obtained.

There is another feature of importance to which the author directed attention, and that is the extra safety obtained by the multiplication of the cylinders. In most cases they are smaller, and therefore less likely to burst than the cylinders of ordinary lifts. On the other hand, the bursting of any one would not leave the cage to descend uncontrolled. The second, and perhaps more important point is, that after the lift has once started no further power can be obtained. There is rarely, therefore, much spare power beyond that necessary to raise the load in the cage; consequently, should a person be caught between the floor of the cage and any part of the enclosure, instead of serious injury to life or limb, the probability is that the lift would simply stop. He had continually tested this by catching hold of some protruding part of the enclosure, and bringing the lift to a standstill; and as, perhaps, one of the most frequent sources of danger is the jamming of a limb or the body between the cage and the enclosure or floor, anything

that tends to mitigate this is of value, and may fairly be said to be a point of the utmost importance.

The arrangement, it is clear, can be adopted for direct-acting lifts with Ellington or other balancing cylinders. A sketch showed a balancing cylinder with three actuating rams, the combined area being equal to the single ram usually provided, and another showed a suitable starting valve and power-setting valve. On the starting valve being moved back to make the ascent, it admits the pressure water through a pipe to the power-setting valve, and at the same time opens the exhaust from the back of the small piston which actuates this valve. The pressure water at once acts on the centre actuating ram, and if this has power enough to raise the lift, the movement of the power-setting valve is stopped by a pawl, but should this ram be insufficient, the piston with the valve moves back slowly, first covering the port leading to the centre ram and then uncovering the port leading to the two outside rams, which act together. If the lift then moves, the further movement is arrested by the pawl; but should these two rams not be sufficient, then the valve moves on still further, opening the two ports leading to all three rams, giving the maximum power. When the lift is stopped, the starting valve is brought into the central position shown, and the pressure water is free to act through the small port and pipe on the back of the piston, thus driving the power-setting valve home to its normal or first position. In lowering, the valve remains in this position, the exhaust water from the two outside rams escaping through the retaining valve shown, or a separate pipe with a retaining valve may be employed, so that the water need only pass through the starting valve in lowering. In cases where the balancing cylinder already exists, two or more small rams can be added, attached to the moving cross-head, and acting in the reverse direction to the existing actuating ram. If the pressure water is admitted into all three rams, the two small rams will oppose the large ram; but as their combined area should only be about two-thirds of the area of the large ram, the water is forced out of the cylinders and finds its way into the large cylinder, therefore only about one-third of the water is used. If the pressure water is admitted to only one of the opposing rams, two-thirds of the water will be used, and if it is admitted only to the large ram, the full power is obtained, and the quantity of water used is the same as before the alteration. It is probable that instead of two rams four would have to be used, two always acting together on opposite sides of the cross-head, so as to give a central strain. If the balancing cylinder is overweighted, so as to raise the empty cage and the attendant without the use of pressure water at all, the lift may be made to lower loads over a certain weight, and store up the energy to bring up the empty cage with the attendant only in it, ready to lower another load. Or the stored up energy may be used to assist in raising the next load, therefore using a commensurate less amount of water. In some of the large stores in London the passenger-lifts are in constant requisition, the cage being nearly always full of passengers both up and down. In cases of this sort it would be easy to so design the machine that very little pressure water would be used. To accomplish this end it would only be necessary to have either opposing rams or pistons, and the power-setting valve arranged to distribute the water to the right cylinders to drive up or down as might be requisite to deal with the load happening to be in the cage at the time. It is obvious that a ram might be employed instead of over-weighting the balancing cylinder, but this would involve returning the water into the mains, and this is objected to where the water is obtained from the Hydraulic Power Company's mains. The arrangement applies to suspended lifts with jiggers, as well as to direct-acting lifts with balancing cylinders.

The arrangements of stopping the further movement of the power-setting valve previously described are perfectly good for a lift, but quite unsuitable for a crane, the conditions of working being altogether different. When a lift is started no further load is expected to be taken into the cage unless it is first stopped, but when a crane commences to raise a load resting on the ground, it does not immediately have to raise the whole weight, but the weight increases as it is raised clear of the ground. Besides this, the loose chain has to be taken up before commencing to raise the load at all, therefore the same arrangement of stopping the further movement of the power-setting valve immediately the machine begins to move is impracticable for cranes. It is, therefore, proposed to interpose in front of the power-setting valve a graduated or stepped stop, moved up or down according to the load on the lifting-chain. When there is no load or only a light load on the chain, the first grade is interposed to prevent further movement of the valve, but as the load increases the stop is moved until it allows the valve to advance to the second or third power, and so on. The stop may be actuated by the tail end, or what is usually the fixed end of the chain, after having passed over the multiplying sheaves on the jigger or multiplying cylinder, or by arranging one of the leading sheaves, over which it passes on a spring or weighted lever, so that it is depressed more and more

as the weight increases on the chain. The same action takes place when the goods are lowered, but in the reverse way. With very little extra cost the crane may be made to lower goods over a certain weight, and return the empty chain ready to lower again without using any water at all, except the little sometimes necessary to raise the load clear of the floor before swinging it clear of the loophole. As in a great many cases as much weight has to be lowered by the crane as had previously been raised, this arrangement alone should save nearly half the pressure water used by a crane on the present system, which uses as much water to raise the empty chain as it would for the full load. The same remark applies with equal force to warehouse lifts, and the same advantage is claimed, that in lowering goods over a certain weight sufficient energy is stored up to return the empty cage without the use of pressure water at all. The energy is stored by raising a weight and not by returning the water to the accumulator or other source.

The next point of interest is the cost of production or manufacture. It is true there are several more parts in a multiple-power jigger than in an ordinary single power one, and there are two valves instead of one. On the other hand, there is the advantage that the parts can all be smaller, and much may be saved by using smaller tools, and in the facility with which the smaller parts can be handled in the factory. Assuming a three power machine, made with three solid rams, the total area of the three rams would only be equal to the area of the one ram in the ordinary machine. The total weight of the rams is, therefore, the same in both cases, but it is granted there is a little more cost in turning the three rams over the one large one. But the small cylinders can be made of wrought-iron or steel tubes, and the three will not weigh more than, if as much as, the one large one, if made of the same material. The three small ones, however, will be quite as cheap, if not cheaper, than the one large one; they are certainly much easier to manipulate; the stuffing-boxes can be small castings screwed separately on to each cylinder or tube; the parts are all, therefore, much reduced in size. But the great advantage would be that these machines could be made and stocked, so that the sizes of the rams need not be different for every load the jigger is constructed to carry. The same machine would be used whether the lift raised a maximum load of, say, 5 or 15 cwt., or any intermediate load. It would not, therefore, be necessary to make a special machine for each job, as is the present practice. The length of stroke would merely be a question of cutting off the rams and tubes to the requisite lengths. All parts could be made to gauge and interchangeable, and it is anticipated that, by making a few special machine tools, and by reducing the manufacture to the multiplication of exactly similar parts, the cost would be little if any more than the present machine, which can rarely be made in duplicate. There would be a very great advantage in being able to take the machine out of stock, and start fixing it almost directly on receipt of an order, instead of having to wait while the machine was being prepared.

There are several inventions which have for their object the saving of water, or to some extent the using the pressure water commensurately with the load lifted, and some of these arrangements are more or less automatic in their action. Mr. John Hastie, in his specification, No. 3,561—1876, appears to be the first to propose anything in this way. He adopts the principle of opening a valve kept closed by a spring when the pressure in the lift cylinder reaches a certain point. Mr. Robert Middleton, of Leeds, comes next, he also adopting the principle of actuating the valves by the varying pressure created in the lift cylinder by the various loads or weights to be raised. Then comes Mr. Thorpe, of the American Elevator Company, who likewise relies upon the varying pressures in the cylinder. There are also others who have worked in this direction, but they either rely on the varying pressure or on moving the valve further by the hand rope when larger power is required. Most of these arrangements would be effected by the varying friction of the pistons moving the valves, or the friction of the machine itself, and therefore cannot be made to work up to close upon the extreme limit of the power of the several grades, but a large margin of power has to be allowed, and for this reason the arrangements cannot be as economical as they otherwise would be.

THE ROYAL SCOTTISH WATER-COLOUR SOCIETY'S EXHIBITION.

FOUNDED in 1878, the Royal Scottish Society of Painters in Water-Colours takes this year a new forward step. For the first time in its history it comes, the *Scotsman* says, to Edinburgh from Glasgow, where its exhibitions have hitherto been held, and contact with the life of the capital, it is hoped, may do the Society good in making its aims more widely known, and in leading the art-loving people in the east of Scotland to take an interest in it. Its exhibition this year is an open one—that is to say, it is not confined to members only, but has been made free to all water-colour artists whose works

reached the necessary standard of merit, and it opens its doors in Edinburgh with the prestige attaching to so gracious a mark of royal favour as it has recently experienced in the knighting of its president, Sir Francis Powell, who has so long and worthily presided over its deliberations. Should the present experiment prove successful, the exhibitions in future will in all probability be held alternately in Edinburgh and Glasgow. Therefore, although the days are fine and the light is long, and people are tempted at this season to be more out of doors than in, it may be hoped that the Water-Colour Society will find a warm welcome in Edinburgh, and that sufficient encouragement will be given to it to warrant the Council in arranging for a return visit. The exhibition is being held in the Mound Galleries, which, with their cool draperies and artistic decorations, are hardly recognisable. Two of the rooms, the first and fourth, are done in old gold of a soft tint, the other two in a particularly pleasing red, which forms an admirable background to the pictures. The upper spaces of the walls are covered with paper in two shades of brown, with a dividing blue band; the floor is laid with a peacock blue carpet, and at the archways are hung light lawn curtains—each alternating set having a delicate green tint. This part of the work has, we believe, been superintended chiefly by Mr. A. K. Brown, A.R.S.A., who, with his assistants, have shown how extremely pleasing decorative effects can be secured with the most simple materials, if rightly used. Statuary has been introduced into the quietly-lighted recesses under the archways, and palms placed at appropriate points give a further summer-like character to the rooms. It was worth while for the Society to come to Edinburgh to show some of the old stagers how these galleries, which lend themselves so readily to be decorated, can be simply and yet effectively treated. Doubtless it will spur on the S.A. Society in October to still further efforts in the same direction, and may even give a hint to the Royal Scottish Academy for its exhibition next February. Even the finest jewels are often improved in appearance by an artistic setting. The exhibition of drawings is admirable. It far excels in merit any of the exhibitions of water-colours this season in London. There are eighty-four members of the Society, and of these sixty-one exhibit. Four hundred and fifty-eight drawings have been hung. These include the work of the best of our water-colour artists in Scotland, and, by invitation, a number of well-known Englishmen exhibit, though nothing very grand has come across the border. The south country men, such as H. Clarence Whaite, the president of the Cambrian Society; Mr. Ernest A. Waterlow, Mr. Walter Langley, Mr. J. H. Henshell and Mr. Colin B. Phillip send representative work, though their drawings are not of outstanding merit. The fact is that though England was the original home of water-colour art, not a few of the Scottish artists have long since outshone their English competitors in the same medium.

On the eve of the opening of the exhibition the members entertained to dinner in the Balmoral Hotel their president, Sir Francis Powell, in recognition of the knighthood which Her Majesty has been pleased to confer upon him. Mr. M'Taggart, R.S.A., the vice-president, occupied the chair.

The Chairman, after the health of the Queen had been duly honoured, proposed "Sir Francis Powell." They had often felt individually and as a Society very much indebted to him. They had all appreciated his unceasing energy for the good of the Water-Colour Society. If Sir Francis Powell was not an actual originator of the Society, he was amongst the very first to favour it, and certainly he was the strongest in assisting them to put it into shape and to carry it forward. He remembered the first exhibition of the Society sixteen years ago, and the success of that exhibition and the success of the Society since had been largely owing to Sir Francis Powell. It had not been all smooth sailing for the Society during that time. Now and then they had had their successes; but they had also had considerable disappointments, and through them all their President, enthusiastic and strong and helpful and full of resource, had sustained and supported and encouraged their efforts. The position they now occupied was largely owing to the exertions of Sir Francis Powell. He had sent many beautiful contributions to the exhibition; they knew his enthusiasm for that branch of art, and his amiable and attractive personality and admirable qualities had kept the Society together, and had enabled them to keep their faces to the front all these years. They had all done their best, no doubt, for the Water-Colour Society, and on that account they appreciated all the more the exertions of their President. Now that the Society had been honoured by the Queen conferring on its President the rank of knighthood, it well became them to drink their President's health, and to wish him long life to enjoy the honour which had been conferred upon him, and more energy to forward anew the interests of the charming art which they all practised.

Sir Francis Powell felt, he said, deeply moved by the many tokens of regard he had received and by their kind words of congratulation. One of the greatest personal pleasures he felt in connection with the honour that had been done to their Society was the many evidences of friendship and of kindness

he had received on this occasion. He had received many letters of kindness from the highest of the land, and he might tell them even little village children had sent him their tiny notes expressing their delight at the honour which had been done to him, and these notes had been the first that he had replied to. It was to him a great delight that this honour had come to their Society at the time when they had such a charming exhibition as was open now in the Edinburgh galleries. It was another pleasure to feel that their members had come forward to render the present really a remarkable exhibition. Mr. McTaggart had recalled to his mind the first exhibition they held in West Nile Street. The room was small, and, comparatively speaking, they had few pictures. Let them consider what they were now. He thought it did the Society honour that in spite of great obstacles they had been able to produce an exhibition like that of the present year. It showed what advance they had made, and how perseverance and determination would in the end bring success. If they would only be enthusiastic themselves and full of determination, the Society would advance still further, and become the head and front of water-colour art in the whole country. It was in their power to do it. It was the enthusiasm of every one that produced a good exhibition. Let them feel themselves a united body. Do not let their power be frittered away or divided by party feeling or anything of that kind. Let them be animated by the unanimous feeling to advance their art, and they would do yeoman service for the Society to which they belonged. He knew quite well they would do that, and such being the case, he had no doubts for the future of the Society. It would prosper in spite of all obstacles; it would grow if that feeling he had referred to bound them together.

Mr. John Smart, R.S.A., in proposing "Success to the Water-Colour Exhibition," said the Society never had a better. It was one which, as members, they might feel proud of, and which he trusted the public would esteem and heartily support. It was the first time they had been able to hold an exhibition in Edinburgh. He saw no reason why these exhibitions should not henceforth be held alternately in Edinburgh and Glasgow. It rested with the Edinburgh public to say whether that should be so or not. He was sorry to say that in Edinburgh of late years there had not been so much enthusiasm in regard to art and art exhibitions as he could remember in former years. He hoped a stronger and a deeper interest in art would be revived, and that on this occasion it would be manifested towards the Water-Colour Society. He heartily agreed with all that had been said of their president. Sir Francis Powell was an Englishman of a type they should be glad to see more of in Scotland, but the fact was that he had been so long in Scotland that he had almost become a Scotsman.

Mr. James Paterson, in proposing "The health of the Vice-President, Mr. McTaggart," said they were all proud of Mr. McTaggart. They had drank the health of their worthy President, and had heralded him as an Englishman in Scotland. Mr. McTaggart, they could all say, was a Scotsman who they were glad had not gone to England. This tendency to excessive centralisation of artists which had tempted so many good men from Scotland to take up their abode in the South, required a firm stand to be made against it; and Mr. McTaggart, he thought, deserved credit for resisting the temptation which undoubtedly a man of his unique talent had experienced, to go away to what perhaps would have been a wider field, and for remaining true to the country in which he was born and the art of which he so highly adorned.

EXCAVATIONS AT ARGOS.

IN the following letter to the Hon. Seth Low, president of the Archaeological Institute of America, dating from Heraion of Argos, Mr. Charles Waldstein gives a report of the excavations at Argos, which have been conducted during the present spring by the representatives of the American school at Athens:—

There is so much to say about our excavations this year that I hardly know where to begin. But I feel that before all I wish to give due recognition to the efficient help which several members of the school gave to our work of excavation. Mr. H. S. Washington, who, as you are aware, has for several years past carried on successful excavations at Plotheia, Plataea and Phlius, at my request came from Leipsic and remained at the Heraion from the beginning to the end of our work, taking charge during my absence, and assisting me throughout in the most efficient manner. Messrs. Lythgoe and Richard Norton, both of Harvard College, were also active during the whole of the campaign at the Heraion, each taking charge of large gangs of men, while Mr. Meader, of the Michigan University, did similar work at the Heraion, interrupted only by the week during which he had charge of the excavations at Sparta.

Owing to the kindness of the prime minister, M. Tricoupis, we were provided with three large tents from the Government stores, and were thus encamped on the hill immediately over-

looking our excavations. The plan of camping out has in every way proved a great addition to comfort, and has enabled us to keep more constant watch over the large body of men whom we employed. Our staff rose to 230 men with thirty-nine carts, and, though much still remains to be done, I believe this season's campaign has pushed the whole task much nearer to completion.

Our good fortune in every direction was beyond my expectations and even my hopes. We first completed the excavations of the earliest Homeric temple, clearing the whole platform, the cyclopean supporting wall of which had always been visible. Immediately below the surface we generally came upon masses of *poros* stone split into small fragments by the heat of the conflagration (which, as you know, took place in 423 B.C., owing to the negligence of a priestess). Below this we came upon a continuous burnt layer of charred wood and other materials, with fragments of pottery and melted bronze fused into one mass, and below this again we frequently came upon whole nests or pockets of pottery in comparatively good state of preservation, of seals, of objects in bronze and other materials which, I believe, will prove of the greatest interest and importance, inasmuch as we may be able to show that these objects antedate the construction of the temple, which again is undoubtedly of the Homeric period. Now, the relation which these finds hold to those of Mycenae, Tiryns and Hissarlik will, I trust, finally close the controversy concerning the date assigned by Schliemann and his followers and by Mr. Flinders Petrie to the Mycenaean works, by giving definite evidence in favour of their early ascription.

We have also cleared away the whole hillside between the first and the second temple, below the cyclopean supporting wall, down to the native rock, and besides the interesting stoa, the steps of which we discovered last year, and the whole of which, with portions of columns *in situ*, is now cleared, we have found interesting buildings connected with baths and water-supply at the west end of the stoa, while to the east three buildings of a later Hellenic period have been laid bare in comparatively excellent preservation and of great interest. Above these and immediately below the cyclopean wall there are remains of rude walls, beyond a doubt belonging to the early houses which I believe to have been the dwellings for the priestesses of Hera in the earliest times.

We have excavated the ground all about the south side of the foundation walls of the second temple (which was built about 420 B.C.), and have begun at the foot of the hill on the south below the stairs we found last year to clear away the earth to the native rock. But at the south-west slope we came upon a new building of exquisite masonry with a considerable portion of the walls standing, on the destination of which I do not now venture to express myself. Immediately in front of these walls at a depth of about 4 feet we found large portions of all the parts of the entablature of the building itself, massed together, and, to our great joy, we discovered the manifest traces of colour upon cornices, triglyphs, metopes and other portions of the Doric order, which will now furnish undoubted evidence with regard to the disputed point of Greek polychrome architecture. We also dug extensively at the south-east corner below the second temple.

Of the different single works of art discovered during these excavations I can hardly give you an adequate idea. I can only say that we filled sixty-three baskets with smaller objects, while there are a large number of marble works and fragments, and that these objects range in date from the earliest pre-Homeric works through all stages of Greek art down to the Roman period. Besides the large mass of important vases there are a great number of terra-cotta figures, among them a complete series of heads of Hera from the earliest date through the best fifth-century art. There are a number of engraved stones and seals, some probably manifesting an hitherto unknown form of early indigenous art, while others are an importation of Phœnician and Egyptian ware. There are also objects in ivory, amber, bronze, lead and other materials, all of the greatest interest.

Finally, we have found three marble heads and portions of the sculptures from the pediments, as well as the metopes which must be ascribed to Polyclitan art. We have found four inscriptions, and tiles mentioning the names of the architects of two of the buildings.

You can well understand how impossible it is for me to give you any detailed account of so rich a find at this moment. We have been hard at work excavating from six in the morning till six in the evening, and then had barely time to arrange our finds and write the necessary notes before going to sleep. Most of the objects hardly have the dirt removed from them. But they are carefully arranged according to the place in which they have been found, and are now being brought to Athens, where they will be locked up in a separate room until early next winter, when I can go to Athens and begin the task of cleaning, arranging and describing so great a treasure. But I hope before then to give a fuller account of our excavations in the next number of our "Journal of Archaeology."

At Sparta, too, we have been very successful. I resumed the excavations of the circular buildings mentioned by Pausanias, which I discovered last year, and left Mr. Meader in charge of the work, who has successfully carried it to a close. The whole building is now cleared, much more of it remaining than I dared hope last year. I venture to believe that it will prove the most interesting building of this date in Greece.

Besides later Roman inscriptions, Mr. Meader found a *boustrophedon* inscription in the building, which well corresponds to the early date which Pausanias ascribes to it. At a village called Choutzopodi (near the ancient Oinoe) we also excavated, Mr. Patton finishing the work. So much for to-day.

I am writing under difficulties and have hardly been able to collect myself after the continuous excitement of our work; for there has hardly been a day, nay, an hour, in which some interesting object has not been brought to light. But I do not wish to keep you, or the friends of the School of Archaeology and the Institute interested in this work, longer than I can help from sharing to some degree the delight of our good fortune.

BRADFORD ANTIQUARIAN SOCIETY.

THE members lately made a visit to Otley, Weston Hall and Leathley. Upon their arrival at Otley they went at once to the church. Here they were met by Mr. C. J. Newstead, who kindly acted as cicerone, and gave a sketch of the history of the church. There was a sacred edifice here in Saxon times, but none of it was remaining. In the chancel and in the north porch there were specimens of Norman work. The Perpendicular east window had taken the place of three Norman windows with round heads. The church was in the form of a Latin cross, and the aisles had been added some time after the rest of the buildings had been erected. The flat ceiling, and the gallery had been removed in 1854. Mr. Fison, who had been a great benefactor to the church, had given a rood-screen, and opened out a window in the tower. Mr. Newstead then went over the numerous monuments, commencing with the altar-tomb of Lord and Lady Fairfax, grandparents of the great Parliamentary general, and mentioning those of Vavasours, Fawkes and others. A beautiful decorated one was to Walter Fawkes, the patron of Turner. The party then drove to Weston, passing to the left the site of the Archbishop of York's Palace, which defended the bridge against the Scotch. The drive to Weston was most charming, the road leading down a fine avenue of elms to the front of the hall, the older portion of which is in the time of Henry VIII., one of the rooms having fine heraldic figures of dragons, dogs, double roses, signifying the union of the Houses York and Lancaster, portcullis, *fleur-de-lis*, &c., on the ceiling. Colonel Dawson met the antiquaries at the garden gate, and took them through the conservatories and the banqueting-hall in the grounds. Mr. George Hepworth took photographs of the hall, and Mr. John Sowden sketched the Fairfax tomb in Otley Church. The Dawson pew in Weston Church contains a stone monument and inscription saying that Sir W. Stopham was buried in the vault below in the thirteenth century. By kind permission of Mr. Fawkes the party drove through the woods and park of Farnley to Leathley, where the rector, the Rev. Henry Canham, LL.B., described the church. He said the lower part of the tower was Saxon, the chancel arch was Norman, and the east window, filled with stained-glass in memory of the late rector, the Rev. Ayscough Fawkes, was Perpendicular. Some of the monuments, especially those of the Lindleys, were interesting. The village stocks were near the church. It had been proposed to have tea on the lawn in front of the rectory, but a violent storm of thunder and rain prevented the scheme from being carried into effect, and it was served in a marquee especially erected for the occasion. Mr. T. T. Empsall, the president, presided, and upon the motion of Mr. C. A. Federer, seconded by Mr. H. J. Barber, of Brighouse, votes of thanks were passed to the vicars of Otley and Weston for leave to see the churches; to Colonel Dawson for permitting them to see over Weston Hall; to Mr. C. J. Newstead for kindly acting as cicerone; and to the Rev. Henry Canham for his description of the church and his generous hospitality.

HOME FOR THE COUNTY COUNCIL.

A LETTER has been addressed by Mr. C. J. Stewart, official receiver of companies in liquidation, to the members of the London County Council, calling their attention to the proposal which he had submitted to them last March for the purchase of that portion of the assets of J. W. Hobbs & Co., consisting of the fine building on the Embankment adjoining the National Liberal Club and twelve houses in Cecil Street. The price, free of all mortgages, is 400,000*l.* Mr. Stewart submits that in many respects the property is admirably suited to the purposes of the County Council, the position being central, the buildings imposing in appearance, and the

site one of the finest in London. The price which has been fixed is, he considers, a very low one, amounting to 5*l.* 8*s.* per square foot, whereas the price of the site recommended by the establishment committee of the Council works out at 7*l.* 13*s.* per square foot. The cost of finishing the main building and making it ready for use is estimated at 60,000*l.* Mr. Stewart describes the property as follows:—"The main part of the building contains a hall, which would be suitable for the Council Parliament Chamber. The measurements are about 74 feet by 54 feet, the height is 28 feet, and there is ample space for capacious galleries. The building is so constructed that the galleries would be conveniently accessible by strangers and pressmen without coming in contact with members of the Council. Part of the original scheme was to build an eastern wing corresponding with the western wing now in course of erection, but this part of the scheme is untouched, and twelve houses in Cecil Street, producing a rental of 865*l.*, are still standing on the site of the proposed eastern wing. Under the courtyard which lies between the main block of building and the Strand are vaults with an underground roadway. The vaults are estimated to produce a rental of 4,500*l.* a year. The main building contains many rooms of very large size (besides those shown on the plan) which seem to be well adapted for the purpose of committee-rooms, and in addition to the large rooms there are over 200 smaller rooms in the main building alone, besides those in the western wing. These smaller rooms are suitable for offices in their present form, or, if desired, can be increased in size at a minimum expense by taking out partition-walls. The buildings are fireproof and soundproof throughout." Mr. Stewart's letter is accompanied by plans showing, among other things, the alterations which would be necessary in order to convert the large hall into a council-chamber. He observes that in the event of the hall not being considered suitable for a permanent council-chamber, the site of the proposed eastern wing, about three-quarters of an acre, would be available for the erection of a new council-chamber, and until it was completed the large hall might be used temporarily.

GENERAL.

The sum of nearly 5,000*l.* was subscribed at a meeting just held of the parishioners of St. Andrew's, Cardiff, for building a new church for the parish at an estimated cost of 8,000*l.*

Dean Lefroy is taking steps for raising a fund of 12,000*l.* for the completion of the restoration of Norwich Cathedral. The Dean hopes to complete the restoration of the entire cathedral by 1896, when will be celebrated the 800th anniversary of its foundation.

An Exhibition of works by local artists, under the auspices of the Dundee Graphic Arts Association, has been opened in the Art Galleries, Dundee.

Plans for the new post-office to be erected in Church Street, Coatbridge, were formally presented to the Dean of Guild Court.

The Marble Statue of William Roscoe, by Sir Francis Chantrey, recently removed from the Royal Institution, Liverpool, was being raised by a derrick to the position it was intended to occupy in St. George's Hall, when, the chain breaking, it fell a distance of about eight feet. The head was knocked off, the nose broken, and the face otherwise mutilated, but the damage can, it is stated, be repaired. The statue was valued at 1,000*l.*, and weighed something like 30 cwt.

Mr. E. Burne-Jones has been elected a member of the Société Nationale des Beaux-Arts, the artists who hold exhibitions in the Champ de Mars.

Messrs. Beaumont, of Manchester, have been commissioned to prepare plans for three chapels which are to be erected in the cemetery of Hyde, near Manchester.

The Durham University Authorities have decided to confer honorary degrees on Mr. Alma-Tadema and Mr. Alfred Gilbert.

The Richmond Corporation intend to purchase the picturesque Thames eyot situated between Brentford and Kew Bridge, an agreement being sealed by which the island becomes the absolute property of the Corporation in perpetuity. The purchase-money amounts to about 400*l.* The Corporation, it is understood, intend to put it in thorough order, with the view to its future preservation and to maintain the beauty of the river at that point.

The Improvement Committee of the Sheffield Town Council recommend that the Council adopt the suggestion of their architect, Mr. E. W. Mountford, to line the walls and principal staircase and corridor of the new Town Hall with various marbles, in accordance with his plan, at an estimated cost of 2,335*l.*—a small sum in regard to the size and importance of the building.

The Architect.

THE WEEK.

ARCHITECTS will remember the admirable drawings of buildings which Mr. WILLIAM SCOTT used to produce. They are also aware that during several years he has made Venice his home, and there he has been accepted as the representative of English art, for Mr. SCOTT's remarkable versatility has enabled him to be as successful in oil-painting, water-colour drawings and in etching as he was as an architect. A collection of some of his etchings of Venice can now be seen at Mr. STACEY's Gallery, 28 Old Bond Street, which is well deserving of a visit, not only from the friends of the artist and architects, but from all lovers of art. There are twenty-five plates, which represent Venice under varying conditions. Mr. SCOTT is no ephemeral tourist; he knows every part of the city, as it were, by heart, and much which he shows will consequently appear novel to many people who are supposed to be well acquainted with Venice. He is not satisfied with representing the exterior of buildings; the views of the interior of St. Mark's will suggest why that building has charmed strangers for centuries, and seems destined to fascinate them still more as time runs on. There is also an interesting view of the Palazzo Rezzonico, where ROBERT BROWNING died, and which now belongs to his son, the painter. One of the best of the plates is a view of Venice from the lagoons, and which reveals the weed-covered silt from which the city arose. The exhibition deserves to be considered as one of the most attractive of the season, and it will give satisfaction to many visitors as evidence of the progress which Mr. WILLIAM SCOTT has made under favourable conditions.

THE annual report of the Liverpool Architectural Society states that there are 125 members, an increase of 10 over last year's number. They comprise 46 fellows, 28 associates, 36 students, and 15 honorary members. The Council hope that before another session begins they will have arranged a system of education with University College which will be beneficial to all young architects and students of architecture, and they hope that their efforts will be reciprocated and that the classes will be well attended. It is regretted that the excursions held in the summer to places outside Liverpool are so sparsely attended, as the younger members ought to benefit considerably by mixing with the older members in this way. The Students' Committee report that the lectures were very well attended for some time, but latterly they showed a considerable falling off in numbers. Home work has been set by each of the lecturers, who have awarded marks to each student. The works sent in proved of a very high order. It was originally intended to hold an examination at the close of the session, but as a sufficient number of candidates did not present themselves, this was not carried out. The committee, however, recommend the Council to award a prize to Mr. C. W. HARRIS, who obtained the highest number of marks for work done during the session. Some account may be given for the falling off in the attendance in the fact of the library being unsuited for the holding of classes, both for sanitary reasons and also that, owing to the non-residence of a keeper on the premises, the lecturers and students have at times experienced a difficulty in obtaining access to the room.

THE programme of the Congress of Architects which was to be held during the week in Paris does not offer any item which would tempt a visitor to cross the Channel. Papers on an archæological exploration in China and on a visionary scheme of a water supply for Paris to be derived from Neufchâtel could be as well read at any time and in any place as in Paris on a sultry day. The eternal discussion about architectural instruction in the provinces suggests how little power the societies have to deal with the subject. Another subject put down for consideration is "du repos hebdomadaire," for English pupils and assistants who may be sighing after the advantages which their brethren in Paris enjoy would do well to remember that the Sabbath is

not always a day of rest in French offices, and the needful reform will never be accomplished by a resolution of any congress. As long as the Société Centrale keeps to a jog-trot course its weakness is known only to the members, who are indifferent, but the annual meetings reveal the fact to outsiders.

THE governing body of the Polytechnic Institute for South London have appealed for aid to assist in securing the sum still necessary for the completion of the scheme. An annual income of fifteen hundred pounds is obtainable on condition that an equivalent sum of fifty thousand pounds is raised by subscription. Up to the present time donations have been obtained to the amount of about forty thousand pounds (including the value of the site presented by Lord CADOGAN), and therefore a sum of about ten thousand pounds still remains to be collected. The governing body have received the authorisation of the Charity Commissioners to carry out a portion of the plans of the building, and the work will be forthwith begun. The Commissioners have further consented to allow the income of fifteen hundred pounds a year to be paid from the date of opening the portion first built, subject to the whole of the required fifty thousand pounds being made up within a strictly limited period. It will not, however, be possible to carry out the scheme in its entirety, or to claim the endowment in permanence, until the remaining ten thousand pounds are secured. Under present conditions it will be necessary in the first instance to omit such vital portions of the recreative side of the Polytechnic as the gymnasium and large hall. But it is obviously desirable, on economical as well as on all other grounds, that the whole building should be erected at once, rather than that the plans should be carried out in portions. Any donations therefore will now be specially valuable, as they will enable the governing body during the present season to undertake building operations on a larger scale, and commence over a wider area the active work of the Institute.

THE auction of the Spitzer collection has ended, and the amount received has amounted to 9,107,931 francs, or about 365,000*l*. The experts who calculated the value of the collection at 400,000*l*. were not far out, for in such cases it is impossible to foresee what may happen, and the bid-dings for many objects are likely to exceed the market value. It denotes the power which antiquity still possesses when we find collectors from many parts of the world struggling for two months in the hope that they may carry off treasures. It is generally understood that an Australian, Mr. GEORGE SALTING, has been the hero of the auction, for his captures have excited the envy of all rivals. Thanks to him, it may be calculated that Great Britain secured a third part of the objects, France another third, and Germany, Austria and Belgium the remainder. The collection of arms has yet to find its way under the hammer, when probably three millions of francs will be obtained by the representatives of M. SPITZER. The proceeds of the sale are sufficient to prove that there is little difficulty in finding enormous sums to gratify the passion for acquiring bric-à-brac.

THE decision which was given on Monday by three judges of the Queen's Bench Division respecting the new block of buildings at the corner of Kensington Court is of vast importance to builders. The site was part of the ground on which Baron GRANT's house stood, and its value was determined by the fact that it faced Kensington Gardens. At the side and behind are the houses forming Kensington Court. For taxation and other purposes the large block will be assessed as part of Kensington Road. The London County Council, however, regarded the block as part of the narrower Kensington Court in order to insist on a reduction of the height. The magistrate who first heard the case declined to take that view, but stated a case. Owing to the cost of taking down, Mr. Justice DAY and Mr. Justice BRUCE desired to have the case reargued before three other judges. On Monday decision was given that the Building Act was violated, and the case was sent back to the magistrate in order that the builders may be convicted. It is a remarkable conclusion.

NOTES, PRINCIPALLY ON ENGLISH "GEOMETRICAL DECORATED" WINDOWS.

III.

BY A CORRESPONDENT.

AT Wellingborough Church, as at Howden, there is a beautiful feature over a large five-light window, as the label has an ogee top with a finial, and the bases of two slender pinnacles sit upon the label and flank a pretty canopied niche in front of the battlemented gable coping. This detail in no way detracts from the importance of the tracery window-head, but on the contrary tends to add to its dignity.

The good proportion of tracery openings, the one with the other, as well as their individual grace of outline, ought to be most carefully considered. Take as an example the beautiful Decorated tracery to the window at Herne Church, Kent, in which this principle is very well observed. Where there is space, trefoils, quatrefoils and cinquefoils are used, the heads of the very wide lights being the only exception where the trefoil cusp looks somewhat large and out of scale. But in windows of that period the cinquefoil-headed light was exceptional. The double sill, the substantial character of mullions and tracery and the due subordination of mouldings in this elegant window are all well worth study. Looking at the Early Decorated windows to the Chapter-house at Wells Cathedral, it is necessary to be almost hypercritical to find a single failing. Everything is so good, including the handsome sills previously commented on. The mullions are also massive and well moulded and the tracery follows suit. The rich jambs with the ball-flower in the hollows and the ogee-headed crocketed and finialed hood-mould give an appropriate crowning finish to the ornate work beneath. It is really only in the balance of forms in the tracery circles of this example where any alteration could be desired. For the two smaller circles are cinque-foiled, just like the central one, though only of about half the diameter. But in another instance, the large five-light Decorated window to the church of the Holy Trinity, Hull, the spherical triangles in the tracery-head contain a trefoil with three smaller trefoils attached, the proportion of the former to the latter being as nearly three to one. This does not seem quite as it should be, and the tracery in other respects is also of somewhat "mixed" character, so that the result is not harmonious.

Referring to a Flowing Decorated east window at Yaxley Church, Huntingdonshire, EDMUND SHARPE remarks that "there is sufficient variety in the design without the occurrence of any strong contrast, and sufficient similarity in the principal features of the tracery, at the same time that the monotony of Flamboyance is avoided." The proper principles of good window tracery are here admirably enunciated. But Mr. SHARPE might have said that even more monotonous than French Flamboyant tracery is the Reticulated, of which so many Mediæval examples are found in England. The very derivation of the name is sufficient to stamp the diaper-like character of such window-tracery, in which any architectural composition, properly so called, is impossible. It is true that in many windows during the whole of the Geometrical Decorated period is found the principle of intersecting tracery, or, to quote Mr. SHARPE, "those in which the mullions bearing the principal tracery-bars are continued through the window-head in arcs of similar curvature, and intersecting one another, terminate in the window-arch." But though the divisions must thus become somewhat equable, the sameness or repetition can never be as great as in the Reticulated style. There is another type of Geometrical Decorated window, of three, four and five lights, where the tracery has no dominant leading lines, and consequently only one order of mouldings is used, the Geometrical forms being arranged to fit together as elegantly as can be managed. This may be pretty, but does not convey to the mind the idea of a well-thought-out architectural composition, and may rather be compared to the ingenuity of the piecemeal planning of a child's puzzle, or the elaborate devices of Moorish ornamentation. There is too much sameness in the parts for good effect. In some windows of the Flowing Decorated period, though the mullions contain two orders, both are continued throughout

the tracery-head, as is often seen in French Flamboyant, and this has not the good appearance of the usual subordination of mouldings in English Decorated examples.

Floriated cusp-points might with advantage be more often used than they are in tracery, as they give variety and richness in a place where it is valuable. The elegant Geometrical two-light Decorated window at Solihull Church, Warwickshire, is an example where all the cusps are embellished so. This specimen is also remarkable for the peculiar shaped foliation in the tracery-head. No necessity, however, exists, as there, to florate all the cusps, and it may well be confined to some central feature in the composition.*

The centre-piece to tracery is generally the leading feature in Geometrical Decorated windows; but it is well not to always lay too much stress on this point, as academic rules are apt to result in stiff-looking work. There is an Early Decorated five-light window at the east end of the refectory to the beautiful abbey at Easby, near Richmond, Yorkshire, which Mr. SHARPE comments on as being remarkable in this respect:—"The large circle which forms the centre-piece is not carried, as is usual, upon the shoulders of two arches, but rests upon two smaller circles; the surface mouldings of these circles do not intersect with those of the centre-piece." An architect at the present day would hesitate before he so constructed his tracery. Nevertheless, the effect is excellent, and shows what a skilful designer, one who knows when to relax, can do.

As containing Domestic examples of window-tracery, the fine Manor house at Winfield, Derbyshire, takes a high place, though there is nothing earlier in it than fifteenth-century work. The beautiful window to the entrance porch of the great hall is remarkable, though square-headed, as looking far more like Decorated than Perpendicular, both in its elaborate tracery-head and in the mouldings to the mullions and jambs, which are of a very rich character, especially internally, where they take the place of a plain splayed reveal. The roll or bowtell is a leading feature instead of the fillet, and in this case with excellent effect. The writer is of opinion that, as a general rule, even where the mouldings and tracery are rich and elaborate, the roll as the central feature in the mullions and head is not so telling, though no doubt more decorative, as the fillet. It is for that reason, probably, that the latter is so much more frequently found than the former. There are some other beautiful windows at Winfield Manor to the bay of the great hall, which *look* considerably later in date, though not much so, than the before-mentioned example, as the window-arch is four-centred, the mullions and jamb mouldings being simple and of a usual Perpendicular type. It is in the transomes where so much richness occurs, as the foliations are inverted, with tracery, so that the transome becomes a more important feature than usual. There is also a very large and fine window to the south end of the "State apartment," which like some of the specimens before alluded to has a crocketed hood-mould surmounted by a carved finial. At the springing line of the window-arch is a transome extending over the two central lights, those at the side having a transome lower down, forming a part of the tracery. Lower down is the regular transome, stretching the whole width of the window in the usual manner. There is a peculiar effect in the upper part of the tracery-head, caused by the first order being carried round in such a manner as to give a kind of shouldered or square-headed trefoil appearance. The three windows at Winfield Manor that have been mentioned are all certainly designed to suit their locale. They are differently treated to Church windows. There are other good examples of windows of Domestic character in the old Manor house which do not call for any particular comment. It would be difficult to find elsewhere in one spot such a number of specimens exhibiting so much variety in design, and the writer being familiar with the building has pleasure in describing some of its interesting points.

The important subject of the due subordination of the mouldings of Decorated windows was very ably worked out

* Carved ornaments might also be more often employed in the jambs, externally, in those happy cases where expense is not so much an object, thus giving additional life and interest to the window.

by EDMUND SHARPE, though at the present day, when Gothic principles are so well understood, some of his comments may appear to give almost elementary information. He remarks on page 51 that "the different orders of the window-arch seldom consist of the same mouldings, and do not often even resemble each other. This is, perhaps, less the case with the earliest windows than with the later ones." He proceeds to say, "On the other hand, the rich series of curvilinear arch-mouldings, commencing with Carlisle and ending with Beverley, exhibit profiles of great variety and beauty." Further on, "As soon, however, as the double ogee began to be a prevalent curve, the practice of repetition in the orders of mouldings, both of windows and doorways, became again very common." All this is very interesting. In some thirteenth-century work there is good reason for saying the mouldings have the effect of bundles of reeds tied together, and this complaint is justified by their sameness, also by the want of proper prominence and boldness to the leading members of the several groups of mouldings. Again, page 53, SHARPE says, "The section of a tracery-bar is usually the same on both sides. This rule, which may be said to obtain throughout the whole of the Curvilinear period, has its exceptions in the Geometrical period. Occasionally the circular centrepiece has a different series of mouldings on the inside and on the outside. . . . Where, also, two orders of Foliation are used, not occurring together, a Tracery-bar will sometimes show a different profile on its two sides." Even were there no Mediæval precedent for what SHARPE has described, there can be no reason whatever why, when the architect thinks fit, he may not act according to the particular circumstances. For example, the employment of what has sometimes been called "edge-tracery" (*i.e.* where the fillet is dispensed with and the plain chamfers or hollow chamfers, as the case may be, meet in an aris) is very useful where the tracery requires to be lightened, more particularly in wood-work. For the same mouldings can be used in the same window with or without the fillet. What is somewhat unfortunately termed a "false" mitre is also handy in those parts of tracery where the plan just mentioned does not suit, so as to get a perforation. Even although an architect gives a drawing of the tracery half or full size, he is sure to find that he can improve it when he has seen the masons set it out full size on the boards, as every architect ought to make a point of doing if he possibly can. It is very apparent that much of old Geometrical tracery was never struck in by compasses, and varies in outline where, according to rule, it ought to be the same. In modern practice such a procedure is undesirable, but at the same time it will be found that an occasional deviation from compasses is a decided help. It was just remarked that some license might be taken in lightening tracery, but, on the other hand, there is occasionally an advantage in giving, at any rate, an *appearance* of strength where desirable by refraining to pierce according to routine. What ought to be avoided is any "cut-and-dried" look to a window. It should show the evidence of the care and thought bestowed upon it by the designer, and not look as if turned out from a mill. To make one last quotation from EDMUND SHARPE:—"Much ingenuity is often shown in the manner in which these three members of a traceried window [*i.e.* window-arch, scoinson-arch and rear-vault] are respectively arranged and united with its lower part and with one another; and the subject is one which deserves more attention and study than is usually bestowed upon it." These words might be written in letters of gold, so true are they. But, happily, since they were penned architects have begun to pay a good deal more attention to the point SHARPE alludes to than they did then. But, with the best intentions, what can the unfortunate architect do who is tied and bound by want of funds placed at his disposal? It is most difficult to find room for a window-arch well recessed from the exterior, an ornamental rear-vault, and a bold drop-arch for internal effect—for it means walls of substantial thickness. The successful treatment of a scoinson arch is important, for it gives a charming variety, and prevents a too large soffit where the window is placed at a considerable height. If treated in combination with an order of tracery distinct from that of the exterior of the window the effect is the more enhanced, as it gives that slight feeling of mystery which is so valuable an aid to the architect.

The writer has now arrived at his limit of space, but trusts that the few observations he has been privileged to make may possess some little interest, being the outcome of some thought, as also of practical experience.

THE BROTHERS VAN OSTADE.*

IN the history of painting there are few circumstances more remarkable than the revolution which took place in Holland when artists renounced the portrayal of imaginative scenes, and holding as it were the mirror up to nature, represented the men, women and children, the animals, the trees, the houses, the fields, canals and the sky which could be seen every day. According to the theories by which epic grandeur was indispensable in everything that claimed to be art, the Dutchmen's efforts will not appear to have much importance. REYNOLDS could only admit that they had "the same right in different degrees to the name of a painter which a satirist, an epigrammist, a sonneteer, a writer of pastorals or descriptive poetry has to that of a poet." As a painter, who was always experimenting, he could not be indifferent to the technique that is visible in the Dutchmen's works, but the President considered it was out of place. The "correct, firm and determined pencil which was employed on vulgar and mean subjects" if he had his way would "without any change be employed on the highest, to which indeed it seems more properly to belong." In the case of another master of the school it was only necessary for him to have been born in Rome, when, as REYNOLDS believed, "the same sagacity and penetration which distinguish so accurately the different characters and expression in his vulgar figures would, when exerted in the selection and imitation of what was great and elevated in nature, have been equally successful, and he now would have ranged with the great pillars and supporters of our art." It could not be foreseen in 1774 that science would compel people to seek after reality in all things, and that poets and painters would have to occupy themselves with something else besides "things unknown."

ADRIAAN VAN OSTADE is one of the painters who convey to us the most accurate notions of Dutch life in the seventeenth century. That life was toilsome. The men who kept out the waters from their fields, and who built houses in swampy places, must have gone through very onerous tasks every day. OSTADE does not show them at work; he preferred to represent his countrymen during their hours of relaxation. The tedium of existence was lightened in simple ways. A game at bowls, the sound of a squeaking fiddle, a pipe of tobacco, a few glasses of beer, a dance, seemed to be sufficient to drive away dull care. His brother ISAAK was more partial to out-of-door scenes, and to some extent supplemented his brother's work. The combination of their pictures gives a very exact representation of peasant life in Holland at one time.

Most of the later biographies tell us that the two artists were born at Haarlem, a town which lays claims to other notabilities. The evidence of their birth is unquestionable, and it is hard to see on what grounds they could at one time be described as Germans and natives of Lübeck. The elder was baptized on September 10, 1610, and the younger on June 2, 1621. The father appears to have been a master weaver. The brothers spent their lives in Haarlem.

FRANZ HALS was at that time living in the town, and ADRIAAN VAN OSTADE became the pupil of a master who, according to REYNOLDS, was better able to express individual character than any other portraitist. Among his fellow pupils was ADRIAAN BROUWER. OSTADE made good use of the opportunities which were to be found in the atelier of FRANZ HALS, for his earliest works denote that his powers were disciplined. The chiaroscuro of his interiors reveals that he had seen and was influenced by some works of REMBRANDT.

It is not, however, on account of their illumination that the paintings of OSTADE are appreciated. The lighting is only one element in their interest, and by means of the humblest hovel becomes attractive. But what mainly

* *Les Artistes Célèbres: Les Van Ostade.* Par Marguerite Van de Wiele. Ouvrage accompagné de 65 gravures. Paris: L. Allison et Cie

constitutes the charm of the pictures is the sense they convey of fidelity to nature. The peasants are never posed; the figures seem as if struck off instantaneously, and the appearance of occasional coarseness does not diminish their real worth. OSTADE'S Dutchmen are a kindly race; they are fond of company, but they also like to have children beside them, and the presence of little boys and girls elevates the character of the commonest beer-house. The people are not a handsome race; there are no figures qualified to serve as models of APOLLOS and VENUSES, and the costume does not make us think highly of the tailors and dressmakers. They stand before us, however, just as nature and sartorial ingenuity made them, and more refined figures would not be able to deal with the difficulties which beset the contemporaries of VAN OSTADE. The painter was faithful to the labourers, for it is rare to find him depicting such a scene as a notary's office. When he represents a painter at work the artist differs little from a peasant, and the old alchemist we see in the picture in the National Gallery also seems like a man who has mistaken his vocation, and the inscription that lies on the three-legged stool, "*Oleum et operam perdis*," is a warning to all who thought of escaping from field work. It is creditable to the amateurs of the time that they could find pleasure in possessing such lowly scenes. They paid good prices to the OSTADES for their reproductions of nature, and there can be no doubt they acted more sensibly than if they expended their florins on mythological scenes or imitations of Italian allegories. The Dutch patrons of art sought pictures as embellishments of their houses, and were on that account obliged to have only small works. There were no churches and few palaces in which painting could be utilised. When a picture was commissioned for a public hall it was intended to be a glorification of the Corporation, like REMBRANDT'S so-called *Night Watch* and VAN DER HELST'S *Schuttersmaaltyd*, and was not therefore far removed from a *genre* piece. Yet with all the restrictions Holland was able to produce in the course of a few years a body of painters of undeniable genius, whose works are now prized mainly on account of those local and temporary peculiarities which in the eyes of some judges made them worthless.

The people who bought the pictures from the artists found more interest in the subjects than is possible with strangers. For them also the colouring must have had peculiar charms. Strangers who can enjoy only occasional glances at Holland may imagine that it is a dull country, and the warmth which is seen in many pictures will to them appear unnatural. FUSELI spoke with contempt of the Dutchmen who succeeded REMBRANDT because, according to the censor, they "were content to tip the cottage, the hamlet, the boor, the ale-pot, the shambles and the haze of winter with orient hues or the glow of setting summer suns." A native, however, would not object to the hues or the glow. ADRIAAN VAN OSTADE in his early pictures gave the effect of a country when cool tones prevailed; afterwards he preferred effects that may be called golden. Is it not evident that with experience he became more courageous, and was not afraid to record the refinements of colour which were around him? In his latest paintings there are parts which are over-glaring, but this is only an indication that, like TURNER, his eyes had become weakened.

About ADRIAAN VAN OSTADE'S life in Haarlem little is known beyond what can be derived from entries in registers. He was a member of the local guild of St. Luke. In 1636 he was selected with others of the Oudeschurz, or artillery veterans, to form part of the civic guard. We also find that he joined another soldierly body, the Arbalatiers. He married MACHTELGEN PIETERSE in 1638. Four years afterwards she died, and immediately the painter consoled himself by a union with a lady whose initials only are recorded, "N. N." When his second wife died in 1666, VAN OSTADE was able to expend no less than forty florins on her funeral. He died in 1685, in his house in the street known as the Nieuwe Kruysstraat, and was buried in the church of St. Bavon. He left behind about two hundred unsold pictures, besides many etched plates.

IZAAK VAN OSTADE was born eleven years after his brother and his teacher ADRIAAN, and he died about twenty-five years before him. He seems to have been of a joyous

disposition, and he preferred out-of-door scenes to interiors. He shows the peasants drinking at the doors of taverns surrounded by trees, and with sunlight brightening the figures instead of crowded or smoky kitchens. His winter scenes reveal that, like a true Dutchman, he found the season to be one of the pleasantest of the year, since it made active exercise a necessity. Brief as was his life, IZAAK produced over a hundred paintings, and English amateurs were among the strangers who earliest appreciated their value. Two of his works, and one by ADRIAAN, were in the Peel Collection, purchased in 1871, and are now in the National Gallery.

The biographies of the two artists by Mdlle. MARGUERITE VAN DE WIELE are evidently inspired by a desire to insure that henceforth it will be impossible for any writer to assert that the VAN OSTADES were Germans. This duty has been fulfilled, and there can be no gainsaying that the painters were by birth, as by disposition, genuine Dutchmen. Many other errors which are repeated in books are also corrected. The authoress is an enthusiast, and the paintings of the VAN OSTADES are explained with a knowledge of the subjects in which research is united to acquaintance with the country and the successors of the people that were represented by the artists. The latest addition to the series is one of the most delightful, and the reproduction of so many rare etchings in the pages enhances its worth.

ARCHÆOLOGY ILLUSTRATED.

THE first number of the first volume of the *Illustrated Archaeologist*, edited by Mr. J. Romilly Allen, F.S.A.Scot., has just appeared under date of June. This new quarterly will have interest for many. The price is nominal, and the magazine is true to title, being profusely illustrated. Among so much that is interesting, perhaps no article will prove more so to architects than that on "Sculptured Norman Capitals at Southwell Minster," by Mr. Romilly Allen. We give the following:—

The existence of a very fine series of sculptured Norman capitals at Southwell Minster, Notts., has long been known, as they are mentioned in the Rev. Canon J. F. Dimock's "*Illustrations of the Collegiate Church of Southwell*," published as far back as 1854. It might have been thought that objects of such supreme interest to students of early Christian art would have attracted the attention of archaeologists before now. This, however, does not appear to have been the case, and the reason for their having remained so long neglected is probably on account of the inaccessible position in which the capitals are placed, high above the floor of the church and partially concealed by the organ on the top of the rood-loft. When the organ was taken down in May 1892, the sculptured capitals could be seen without difficulty, and some admirable photographs were taken by Mr. A. J. Loughton, of Southwell. It is with extreme regret that we learn that the capitals are now again hidden, with the exception of the sides facing the nave, and these can only be seen with the aid of a ladder. The Ecclesiastical Commissioners' architect, under whose charge the fabric of the Minster is placed, is Mr. Ewan Christian, and the new organ was built by Messrs. Bishop & Sons.

It is a great pity that these gentlemen could not between them have devised some means by which their "kist o' whistles" might have been so arranged as not to interfere with the view of the sculptured capitals, which presumably were intended by the Norman architect to be seen. As a general rule, the better the architect the greater his contempt for the work of his predecessors. Under these circumstances we feel sure Mr. Ewan Christian will pardon our expressing our opinion that he is a good architect.

The sculptured Norman capitals at Southwell are those which support the eastern arch of the central tower of the Minster. There are three capitals on each side, the inner order of the arch moulding springing from the larger ones in the middle of the jambs, and the outer orders from those on each of the angles of the jambs. The peculiar form of the capitals, with a square projection in the middle and volutes at the corners, is characteristic of Norman work of the end of the eleventh or beginning of the twelfth century. There are examples in England at Lincoln and Norwich Cathedrals, and at St. John's Chapel in the Tower of London. M. de Caumont, in his "*Abécédaire d'Archéologie*," informs us that this kind of capital is the most simple and at the same time the most common which is to be found in churches of the eleventh century in France, more especially in the central and north-eastern districts. These capitals are generally plain, as at St. Nicholas's Church at Caen (*circa* A.D. 1100), but there are instances

decorated with figure subjects at St. Benoît sur Loire and elsewhere.

The date of the sculptured capitals at Southwell, as determined by comparative archæology, corresponds very nearly with that assigned to them by history. The Rev. Canon J. F. Dimock, in a paper in the "Journal of the British Archæological Association" (vol. viii. page 265), on the Church of the Blessed Mary the Virgin, of Southwell, tells us that the ancient register of Southwell, called the "White Book," contains a letter from an Archbishop of York, named Thomas, addressed to all his parishioners of Nottinghamshire, in which he prays them to "assist with their alms to the building of the church of St. Mary of Suwell." There were only two Archbishops of York, named Thomas at this period, one A.D. 1070 to 1100, and the other A.D. 1109 to 1114. Canon Dimock thinks that the second of these two is more probably the one who wrote the letter in question. The subjects on the Southwell capitals are all scriptural.

Mr. Romilly Allen then proceeds to describe them, but it is necessary that the fine illustrations should be looked at to appreciate the work described.

There is much of interest in "The Cup of Ballafletcher," by Mr. E. Sidney Hartland, which contains descriptions of the fairy cups and horns, and the legends attaching to them.

The famous Oldenburg Horn, preserved at the palace of Rosenborg, at Copenhagen, is, he says, another vessel to which a fairy origin is attributed. The earliest account of it is found in Hamelmann's "Oldenburger Chronik," written late in the sixteenth century; and the same story in all essentials is still repeated by the Oldenburg folk. The story is that, on July 20, 990, the then Count of Oldenburg was hunting in the forest of Bernefeuer, when he started a roe and followed it to the Osenberg, distancing all his attendants. The weather was hot, and the Count, thirsty with his ride, wished audibly for a draught of water. Scarcely had he uttered the wish when the hill opened and a lovely damsel appeared with this horn in her hand and offered him drink. Not liking the look of the beverage, he declined to drink. Whereupon she pressed him to do so, assuring him that it would go well with him and his thenceforth and with the whole house of Oldenburg, but if he refused there would be no unity from that time forth in the family. He put no faith in her words; instead of drinking he poured out the contents, which took the hair off his horse wherever they splashed him, and galloped away with the horn. An examination of the vessel shows that it belongs to the middle of the fifteenth century. It is of silver-gilt, bearing enamelled coats-of-arms and inscriptions to the effect that it was made for King Christian I. of Denmark, in honour of the three kings of Cologne.

The museum at Bergen in Norway contains several horns of a similar kind. One of them is said to have been presented filled with drink by a troll-wife in Hallingdale, one Christmas Eve, to a man named Gudbrand Godberg. He threw the drink over his shoulder and rode off with the horn. The troll cursed his posterity down to the ninth generation to be afflicted with some bodily blemish, and it is said the curse was literally fulfilled. This horn is encircled by a strong band of gilt copper, inscribed with the names of the three kings, and bears an oval crystal set in a plate also of gilt copper. In the museum at Arendale is a horn known as the Oiestad horn, which was an heirloom in the family of a man whose daughter eloped with her lover on St. John's Day. Pursuing them he was stopped by a troll, who offered him drink in this horn. He flung out the contents, which, falling on his horse's loins, burnt the hair off and fled. Fortunately he was delivered from pursuit by the crowing of a cock, and at length caught his daughter, and stabbed her lover to death. The horn is encircled with rings of silver gilt, and bears an inscription invoking the blessing of God and the three kings on the drink of their servants.

Sweden, too, rejoices in several of these treasures. A drawing of one of them, for which I am indebted to Professor Dr. George Stephens, appeared in the *Illustreret Tidende* of Copenhagen in the year 1881. The story attached to it relates that one Christmas night, in the year 1490, Fru Cissela Ulftand, the lady of Ljungby, in Scania, heard from her mansion a sound of revelry proceeding from a great stone on her estate known as the Magle stone, and sent one of her boldest servants to see what was going on. He found the stone raised, and the trolls dancing noisily beneath it. A beautiful female stepped forth, and presenting to the guest this drinking-horn and a pipe, requested him to drink the troll king's health and blow in the pipe. Instead of complying, he seized both the horn and pipe and galloped back to his mistress, pursued by the trolls in full cry. They offered prosperity and riches to the lady if she would restore the pipe and horn, but she persisted in keeping them, and they are still preserved at Ljungby. The adventurous servant, however, died three days after; his horse died on the second day; the mansion has been twice burnt, and the Ulftand family has never prospered since the theft from the trolls. The horn is stated to be of an unknown

mixture of metals, with brazen ornaments, and the pipe to be a horse's leg-bone.

In various churches of Denmark there are said to be chalices of which legends akin to these are told. At Aagerup a man went down on Christmas Eve to see the trolls making merry. He spent the night with them, and as he departed they invited him to come again next year. A troll maiden then brought him a stirrup-cup. He, however, had his suspicions, so, casting behind him the contents of the cup, he spurred his horse and rode away. The trolls followed, but had a difficulty in keeping up with him so long as he rode on ploughed land. When he took to the highway they gained on him, so that he was in great danger. At length he reached the churchyard, and threw the cup over the wall into the consecrated enclosure, where they could not get it. It is described as of gold. The liquor, where it touched the horse's back, took off the hair.

In "A very ancient Industry," Mr. Edward Lovett describes what is probably one of the sole remaining industries that can be traced back as practised by the very earliest aboriginal inhabitants of these islands, and still carried on in the village of Brandon, situated on the borders of Suffolk and Norfolk, is an industry connected with the Stone Age, and consisting in the manufacture of gun-flints, &c. "Half an Hour in the Grosvenor Museum, Chester," a "Saxon Doorway at Somerford-Keynes," will also interest the readers.

LIVERPOOL ARCHITECTURAL SOCIETY.

THE members of this Society, to the number of about fifty, paid a visit to the interesting house which has recently been built for Mr. R. W. Hudson upon the western slope of Bidston Hill. The party was met at the entrance by the owner and Mr. E. A. Ould, of the firm of Grayson & Ould, the architects of the building, and two hours were spent in examining the various works, after which a portion of the visitors proceeded to the Bidston Observatory, where they were met by Mr. W. E. Plummer, M.A., F.R.A.S., the astronomer, who explained to an interested audience the many scientific instruments under his charge.

Bidston Court is one of the remarkable houses which has been built in this neighbourhood for many years. The visitors entered the grounds through the spreading archway of eighteenth-century wrought ironwork, pausing only to notice the lodge, the outside of which is richly decorated with embossed plasterwork in panels, containing allegorical subjects illustrating the progress of youth to old age, and dawn to sunset. Turning abruptly to the left they passed under the far projecting gables of the north wing into the court-yard, little prepared for the array of fantastic timber gables, bays and dormers which form inwards round a court some 50 feet across. This court has been excavated out of the hillside 17 feet below the road, and is protected on the eastern side by a wall of solid sandstone rock. Even the sweeping winds of Bidston Hill will find it difficult to get into this quiet spot, and the sunshine which streams over the low buildings on the south side of the court is the only intruder. The extraordinary strength and massiveness of the timbers is strikingly combined with a lightness and grace which the profusion of delicate carving and fretwork give to the whole. Conspicuous in one corner rise the beautiful twin bays, gabled on every face, copied as closely as possible from old Moreton Hall. These form the keynote of the whole composition, and an effort has been made to work up to the spirit and refinement which breathes in every line of these charming windows. Upon them is carved in quaint but legible characters the inscription:—"This house was built by Robert Hudson and Gerda, his wife, Anno Dom. MDCCCXCI., these bay windows being copied from those at old Moreton Hall, in the hope that when they have perished these may remain." This explains the motive for reproducing them so exactly, for the original are in a sad state of decay. Upon beams in the gables of the porch and the great hall are the quaint verses—

When the trees are white with rime,
And the ground is black and bare,
Warmth and welcome ye shall find
Underneath these gables fair.
Charitie and jollitie
Carve on every beam of wood;
Mercie, truth, equalitie,
Man's eternal brotherhood.

Passing out of the courtyard and round the gable of the south wing another surprise was in store, for facing the whole length of the south front is the quaintest of little Dutch formal gardens, centreing round a beautiful old marble fountain which came from a palace in North Italy. The south front is less broken up than those facing the courtyard, but it harmonises admirably with its surroundings. The western façade is also rich in "black and white," but it is so shut in with Scotch firs that only occasional glimpses of it can be seen. Standing on

the topmost of a series of grassy terraces and looking over the beautiful formal garden below studded with trim yew trees, we obtain a charming view of the Welsh hills to the left, and to the right the mouth of the Mersey and the Welsh coast as far as Orme's Head. The stables, which are being erected upon the southern boundary of the property, are also black and white, and promise to be as picturesque as the house. What

must strike everybody about Bidston Court is the appearance of age which it has put on in less than two years. A brick or stone house in this position would look a parvenu for twenty years; but the house, not yet inhabited, might have been there for a hundred years, its timbers already silver-grey and its flag roof stained and bleached. This style seems to sympathise and harmonise with its natural surroundings.

"THERE is a place called Somersby, in Lincolnshire," writes Mrs. Anne Thackeray Richie, "where an old white rectory stands on the slope of a hill, and the winding lanes are shadowed by tall ashes and elm-trees, and where two brooks meet at the bottom of the glebe field." It is a place far away from us in silence and in distance, lying upon the "ridgèd wolds." They bound the horizon of the rectory garden, whence they are to be seen flowing to meet the sky.

I have never known Somersby, but I have often heard it described, and the pastoral country all about, and the quiet scattered homes. One can picture the rectory to one's self with something of a monastic sweetness and quiet; an ancient Norman cross is standing in the churchyard, and perhaps there is still a sound in the air of the bleating of flocks. It all comes before one as one reads the sketch of Tennyson's native place in the "Homes and Haunts of the British Poets":—"The village not far from the fens, in a pretty pastoral district of softly sloping hills and large ash trees. . . . The little glen in the neighbourhood, called by the old monkish name of Holywell." Tennyson sometimes speaks of this glen, which he remembers white with snowdrops in the season; and who will not recall the exquisite invocation:—

Come from the woods that belt the grey hillside,
The seven elms, the poplars four
That stand beside my father's door,
And chiefly from the brook that loves
To purl o'er matted cress and ribbed sand,
Or dimple in the dark of rushy coves. . . .

Oh hither lead thy feet!
Pour round mine ears the livelong bleat
Of the thick-fleeced sheep from wattled folds,
Upon the ridgèd wolds.

H. B. D.

THE BIRTHPLACE OF TENNYSON.

From a Water-Colour Drawing by Mr. H. P. Burke-Downing, A.R.I.B.A.

TESSERÆ.**Drury Lane Theatre.**

THE first theatre on the site of the present edifice was opened on April 8, 1663, by the King's company, under Thomas Killigrew, with Beaumont and Fletcher's play of "The Humorous Lieutenant." This house was burnt down in January 1671-72, and the new one, designed by Sir Christopher Wren, was opened with a prologue and epilogue by Dryden, on March 26, 1674. Two theatres were found sufficient for the whole of London in the time of Charles II., viz. the King's Theatre, under Killigrew, in Drury Lane, and the Duke's Theatre, under Davenant, first in Lincoln's Inn Fields, and secondly in Dorset Gardens. One was subsequently found sufficient, and on November 16, 1682, the two companies began to play together for the first time in Drury Lane. Dryden supplied both prologue and epilogue on this occasion. The Drury Lane of Wren was new-faced by the Brothers Adam before Garrick parted with his shares. A new house, the third, was built by Henry Holland, and opened March 12, 1794. This was destroyed by fire on the night of February 24, 1809, when the fourth edifice was erected and opened October 10, 1812, with a prologue by Lord Byron. This memorable fire and the advertisement of the committee for an occasional prologue gave rise to the "Rejected Addresses." Mr. B. Wyatt (the son of James Wyatt) was the architect, and the first stone was laid October 29, 1811. Here is Cibber's description of the interior of old Drury Lane:—"As there are not many spectators who may remember what form the Drury Lane Theatre stood in about forty years ago (1700), before the old Patentee, to make it hold more money, took it in his head to alter it, it were but justice to lay the original figure, which Sir Christopher Wren first gave it, and the alterations of it now standing, in a fair light. It must be observed then that the area and platform of the old stage projected about 4 foot forwarder, in a semi-oval figure, parallel to the benches of the pit; and that the former lower doors of entrance for the actors were brought down between the two foremost (and then only) Pilasters, in the place of which doors, now the stage boxes are fixt. That where the doors of entrance now are there formerly stood two additional side-wings, in front to a full set of scenes which had then almost a double effect, in their loftiness and magnificence. By this original form the usual station of the actors, in almost every scene, was advanced at least 10 foot nearer to the audience than they now can be."—Cibber's "Apology," p. 338, ed. 1740. The principal entrance to Wren's Theatre was down Playhouse Passage. Over the stage was "Vivitur Ingenio." Drury Lane Theatre, though not actually in Drury Lane, derives its name from the Cockpit Theatre in Drury Lane, where Killigrew acted before he removed to the site of the present theatre. The first Drury Lane Theatre (so called) was often described as the theatre in Covent Garden. Thus, under February 6, 1662-63, Pepys writes, "I walked up and down and looked upon the outside of the new theatre in Covent Garden, which will be very fine"; and thus Shadwell, in the preface to "The Miser," "This play was the last that was acted at the King's Theatre in Covent Garden before the fatal fire there."

Painters' Architecture.

Gilpin observes that "a piece of Palladian architecture (which presumably is only another term for regular Grecian architecture) may be elegant in the last degree; the proportion of its parts, the propriety of its ornaments, the symmetry of the whole, may be highly pleasing, but if we introduce it in a picture it immediately becomes a formal object and ceases to please." He adds, "should we wish to give it picturesque beauty we must from a smooth building turn it into a rough ruin." Were this really the case we must give up Claude as a landscape painter, for he not only has introduced a number of perfect, regular and smooth pieces of architecture into his pictures, but they frequently occupy the most conspicuous parts of them. It may even be doubted whether he may not have painted more entire buildings as principal objects than he has ruins, though many more of the latter as subordinate ones. Claude delighted in representing scenes of festive pomp and magnificence as well as of pastoral life and retirement; but if we suppose his temples abandoned, his palaces deserted and in ruins, the whole character of those splendid compositions which have so much contributed to raise him above the level of a mere landscape painter, would be destroyed. But with regard to entire buildings in contradistinction to ruins, the backgrounds and landscapes of all the great masters (particularly of N. and G. Poussin) are full of them, and the ruins few in proportion, so much so, that in the numerous set of Gaspar's, by Vivares, there are scarce any ruins to be found among numberless entire buildings. No painter more diligently studied picturesque disposition and effect than Paul Veronese, yet architecture of the most regular and finished kind forms a very essential part of his magnificent compositions. Many of these splendid edifices have the most truly beautiful appearance in pictures, especially

when they are accompanied (as in Claude's) by trees of elegant forms, and by a scenery, each part of which accords with their character. Gilpin's position might be reversed, and with more truth it could be asserted, that a piece of Palladian architecture, however elegant, however well proportioned its parts, however well-disposed and selected its ornaments, how perfect soever the symmetry of the whole, yet in the mere elevation, or placed (as it frequently is in reality), at the top of a lawn, naked and unaccompanied, is a formal object, and excites only a cold admiration of the architect's ability, but when introduced in a picture becomes a highly interesting object and universally pleases. It should be introduced as the best masters have introduced and accompanied such buildings, for there can be no doubt of the tendency of all regular architecture to formality. The skill with which that formality has been avoided by the great painters, without destroying smoothness or symmetry, is perhaps one of the strongest arguments for studying their works for the purposes of improvement.

Thirteenth-Century Gothic.

The thirteenth century was to the Mediæval art what the Periclean and Augustan ages were to the Greek and Roman; and in each case, though war and bloodshed are in themselves hostile to art, there can be no doubt that the excitements of the human mind resulting from great national struggles have tended to produce that advance in art which followed, in one case the glorious assertion of national independence, in another the conquest of the world, and in a third the romantic and unselfish efforts of the Crusaders. It was a period of deep-seated mental excitement, of a prodigious upstirring of the human intellect. Our learned men at the present day may smile at the quaint and imperfect erudition of these early periods of our civilisation, but they should remember that they were our days of youth, of warmth, and of rising vigour, while the more perfected literature of our own age may possibly be found to superadd to its maturity a few symptoms of old age. This youthful energy pervaded every branch of art; everything seemed to experience a new, a generous, and a vigorous impulse. All Europe became filled with the productions of the newly generated art; every city became a repertory of noble and sublime architecture, and every town and village became possessed of productions equally beautiful, if more modest in their pretensions; while the intervening country was studded over with castles and monastic establishments, in which the same majestic art displayed itself in ever-varying forms, each suited to meet their different requirements. Nothing is more difficult than to describe a perfected art, and the fact is that there is neither in France nor in England any marked difference between the styles during the later period of its transition, and when perfected beyond that unity and consistency of parts which indicate maturity. In France particularly this is the case; for neither had the style there continued long to evince its transitional state by the retention of strictly Romanesque features—unless the square abacus can be so designated—nor did it when perfected throw off, as in England, that one detail which to our eye seems a relic of transition. The later transition and the earlier perfected specimens seem in France to be the same art, a little more developed and more homogeneous, rather than to have many describable points of difference. In England the change of the abacus from the square to the round form makes the distinction more marked, so that English examples at the opening of the thirteenth century always appear later and more advanced than contemporary French ones. In the four examples of perfected Early English—the eastern transept of Lincoln, completed about 1200; the eastern chapels at Winchester, about 1204; the western portals of St. Albans, finished about 1205; and the western porch or Galilee at Ely, finished about 1214—none of them show any remains of transitional character, and all having the English round capital in full development, appear to the English eye more advanced than such works as the western portals of Notre Dame, at Paris, which are, if anything, somewhat later in date. In this country, in fact, the form of the abacus is the distinguishing feature between the transition and the perfected style, while in France there is no such distinction to be found. The difference is more one of feeling, which the practical eye perceives at once without being able to define.

Mass in Building.

The relative majesty of buildings depends more on the weight and vigour of their masses than on any other attribute of their design; mass of everything, of bulk, of light, of darkness, of colour, not mere sum of any of these, but breadth of hem; not broken light, nor scattered darkness, nor divided weight, but solid stone, broad sunshine, starless shade. There is not a feature, however apparently trifling, to which the principle cannot give power. The wooden fillings of belfry lights, necessary to protect their interiors from rain, are in England usually divided into a number of neatly-executed cross-bars, like those of Venetian blinds, which, of course, become as conspicuous in their sharpness as they are un-

interesting in their precise carpentry, multiplying, moreover, the horizontal lines which directly contradict those of the architecture. Abroad such necessities are met by three or four downright penthouse roofs, reaching each from within the window to the outside shafts of its mouldings; instead of the horrible row of ruled lines the space is thus divided into four or five grand masses of shadow, with grey slopes of roof above, bent or yielding into all kinds of delicious swells and curves, and covered with warm tones of moss and lichen. Very often the thing is more delightful than the stonework itself, and all because it is broad, dark and simple. It matters not how clumsy, how common the means are that get weight and shadow—sloping roof, jutting porch, projecting balcony, hollow niche, massy gargoyle, frowning parapet; get but gloom and simplicity, and all good things will follow in their place and time; do but design with the owl's eyes first, and you will gain the falcon's afterwards.

Horizontal and Vertical Disposition of Concrete.

When concrete is used to obviate the yieldingness of the soil to pressure expanse or extent of base is required to answer the end, and to secure this effect, the concrete being widely spread, should be thick or deep only with reference to its own power of transmitting to the ground the weight of the wall to be built upon it, without breaking across or being crushed. But when concrete is used as a substitute for a wall in carrying a wall down to a low level, it is in fact a wall, wide only in proportion to its comparative weakness in the absence of manipulated bond in its construction, and encased by the strong soil within which it is placed. Whether the proper object be the attainment of a sufficiently-expanded base upon a weak soil, or of the sufficient depth below ground in a strong soil, it may be, to exclude meteoric influences, the erroneous notion is that a foundation is rendered strong in the use of concrete by depth rather than by extent of base, and in consequence of this notion heavy buildings are sometimes jeopardised by the friable concrete foundation being placed on its edge instead of being laid flat to cover the breadth of soil necessary to withstand the weight of the superstructure. Concrete, indeed, is at all times more safely to be regarded as a substance to be placed as a layer than as a substance to be set up as a wall, for although with good materials, careful manipulation and patience, excellent erections as walls may be made of concrete, as erections in the same form may be made of tempered clay, neither concrete nor tempered clay is to be regarded as a proper substance with which to form the lofty walls of buildings in towns.

Casing of Hot-water Pipes.

Much of the real danger to buildings from fire would be diminished by preventing that degree of proximity between timber and all such things as can lead to its combustion. James Braidwood, who was the superintendent of the London Fire-engine Establishment, once stated in evidence before a Committee of the House of Lords, that his belief, from observation of many instances, that by long exposure to heat not much exceeding that of boiling water, timber is brought into such a condition that something like spontaneous combustion takes place; that the time might be eight or ten years; that is to say, it may have taken so long for the heat from pipes charged with or used to convey steam, hot water or heated air laid among the joists of a floor or in the heart of a partition, or elsewhere in a building encased in timber, to induce the condition necessary to the actual ignition of the timber. One case was that of Day & Martin's blacking manufactory, which was heated by means of hot water passing through iron tubes into the various parts of the building. In December, 1844, the wooden casing and other woodwork about the upright main pipes were found to be on fire, and from no other cause that could be discovered than the constant exposure for a long time of the wood to heat from the pipes. In this case the pipes were not in contact with the wooden casing, but they were stayed and kept upright by cross fillets of wood which touched them, and these it was which appeared to have taken fire. The small circulating pipes which conveyed the hot water throughout the several chambers, were raised from the floor to about the extent of their own diameter, and the floors showed no signs of fire where the pipes were so removed; but in every case where the prop or saddle which held the pipe up from the floor had been displaced and the pipe had been allowed to sag and touch the floor, the boards were charred. It was understood that the temperature of the water in the pipes never much exceeded 300 degrees.

The Picturesque and the Beautiful.

Among painters Salvator Rosa is one of the most remarkable for his picturesque effects, and in no other master are seen such abrupt and rugged forms, such sudden deviations both in his figures and his landscapes, and the roughness and broken touches of his pencilling admirably accord with the objects they characterise. Guido, on the other hand, was as

eminent for beauty. In his celestial countenances are the happiest examples of gradual variation, of lines that melt and flow into each other; no sudden break—nothing that can disturb that pleasing languor which the union of all that constitutes beauty impresses on the soul. The style of his hair is as smooth as its own character and its effect in accompanying the face will allow; the flow of his drapery, the sweetness and equality of his pencilling, and the silvery clearness and purity of his tints, are all examples of the justness of Burke's principles of beauty. But the works even of this great master show us how unavoidably an attention to mere beauty and flow of outline will lead towards sameness and insipidity. If this has happened to a painter of such high excellence, who so well knew the value of all that belongs to his art, and whose touch, when he painted a St. Peter or a St. Jerome, was as much admired for its spirited and characteristic roughness as for its equality and smoothness in his angels and Madonnas, what must be the case with men who have been tethered all their lives in a clump or a belt? There is another instance of contrast between two eminent painters which confirms the alliance between roughness and picturesqueness, and between smoothness and beauty, and shows, in the latter case, the consequent danger of sameness. Of all the painters who have left behind them a high reputation, none perhaps was more uniformly smooth than Albano, or less deviated into abruptness of any kind; none also have greater monotony of character; but, from the extreme beauty and delicacy of his forms and his tints (particularly in his children) and his exquisite finishing, few pictures are more generally captivating. His scholar, Mola (and that circumstance makes it more singular) is as remarkable for many of those opposite qualities which distinguish Salvator Rosa, though he has not the boldness and animation of that original genius. There is hardly any painter whose pictures more immediately catch the eye of a connoisseur than those of Mola, or that less attract the notice of a person unused to painting. Salvator has a savage grandeur, often in the highest degree sublime; and sublimity in any shape will command attention. But Mola's scenes and figures, for the most part, are neither sublime nor beautiful; they are purely picturesque; his touch is less rough than Salvator's; his colouring has, in general, more richness and variety; and his pictures seem to be the most perfect examples of the higher style of picturesqueness, infinitely removed from vulgar nature, but having neither the softness and delicacy of beauty nor that grandeur of conception which produces the sublime.

Pagan and Christian Catacombs.

The object of the heathen excavators was simply utilitarian; they wanted stone or sand, and they wanted as much of it and with as little difficulty as possible; the object of the Christian excavators was utilitarian also, but of another kind; they wanted places for burying their dead, and places of assembly for the living; but they were hampered with a very troublesome condition—the necessity of concealment. Their modes of operation, therefore, would be altogether different; the ordinary sandpits and quarries would be as near the surface of the earth as the sand and stone could be found; their roads would be as wide and as high as the nature of the rock would permit; and they would have as many entrances to the highroads or open fields as was compatible with the due preservation of the soil for its proper agricultural produce. The Christians, on the contrary, would avoid a multiplicity of entrances, would economise their space and labour by having narrow paths, and would employ every available mode of concealing their works altogether. And these opposite characteristics are so indelibly impressed upon the excavations in the neighbourhood of Rome, that it is scarcely possible to mistake those of one class for those of the other. A visit to the catacombs of St. Agnes brings before us specimens of both; and with this favourable opportunity of comparing their differences, the contrast cannot fail to be striking even to the most careless observer. The sepulchral ways of the catacombs do not average the width of an English yard (not more, in fact, than 2 feet 9 inches); those of the sand-pit, on the contrary, range from 10 to 16 or 17 feet, offering an easy transit not only to slaves and beasts of burden, but even to carts, that might be employed in the extraction of the sand; and the roads of a subterranean stone quarry are often ten times as wide as this; owing to the greater solidity of the material. The galleries of the catacombs are straight and regular, both for economy of space and for the convenience of sepulture, which, in the irregular and serpentine roads of the arenariæ, would scarcely be practicable; their walls too, that is, the natural sides of these galleries, in the catacombs are always perpendicular, and in no other way could the soil be made to bear a number of corpses laid in horizontal shelves, one over the other, and each shut up in its place with heavy tiles or marble; the passages of the arenaria, on the other hand, have no upright sides at all, but the arch of the roof springs from the very ground, so that, supposing two graves to be excavated, one above the other, the outer edge of the upper one must fall for want of support.

ILLUSTRATIONS.

THE QUEEN'S HOTEL, OLD COLWYN, DENBIGHSHIRE.

THE Queen's Hotel, Old Colwyn, was built by Mr. GEORGE NAPIER on the estate belonging to the Old Colwyn Land and Building Company. The hotel contains large dining-room, drawing-room, smoke-room and billiard-room on the ground floor, and a large number of bedrooms and sitting-rooms on upper floors. The site is on the side of the hill, and commands excellent views over the sea and along the coast towards Llandudno and Penmaenmawr. The work is carried out on the street base to level of ground floor and above with Ruabon facing bricks; the upper storeys are constructed with timber facing filled in with cement panels, and the roof is covered with red tiles. The architects are Messrs. J. W. & R. F. BEAUMONT, of Manchester.

CHURCH OF ENGLAND SOLDIERS' INSTITUTE, WOOLWICH.

THE illustration we publish this week is of the new Church of England Soldiers' Institute, now being erected at Woolwich from the designs of Messrs. NEWMAN & NEWMAN, of 31 Tooley Street, London Bridge. The principal entrance opens into the staircase hall, on the right of which is situated the bar, 44 feet by 15 feet, with a separate entrance from the road, and kitchen and servery in the rear; and on the left are two private rooms and a large billiard-room. In the basement the accommodation comprises a large room, 30 feet by 16 feet, to be used for devotional purposes, the secretary's office and the scullery, with lift, larders, stores, &c., together with heating chamber and coal cellar. On the first floor is placed the large concert hall, 54 feet by 26 feet, with retiring-rooms and separate staircase to same at back of stage, and the library, 30 feet 9 inches by 16 feet 6 inches, with music and writing-rooms, are in the eastern end of the building. Eight bedrooms are planned in the attics. The hot baths, lavatories, &c., have been placed in the western portion of building, with a separate entrance to the road. The exterior of the building is faced with red bricks, with red Dumfries stone cills and dressings, and the roof is covered with green Westmoreland slates. Mr. J. BULLERS, of Bermondsey, is the contractor, and the heating and hot-water apparatus is being carried out by Messrs. HAYWARD & POOLE. The total cost of the building will be 5,083*l*.

WURZBURG.

ROYAL INSTITUTE OF BRITISH ARCHITECTS.

THE concluding meeting for the session was held on Monday evening. Mr. J. Macvicar Anderson, president, received the members and visitors, many ladies being present on the occasion, and at 8.30 took the chair in the meeting-room and gave the following address:—

Royal Gold Medal.

The PRESIDENT said:—For the third time it becomes my privilege as your representative to present the Gold Medal which Her Majesty the Queen graciously confers each year on such distinguished architect or man of science of any country as may have designed or executed a building of high merit, or produced a work tending to promote or facilitate the knowledge of architecture in the various branches of science connected therewith. Two years since I was permitted to be the medium of conferring this honour on an eminent English architect, whose name and works are alike appreciated and known by all in the realm of art, Sir Arthur Blomfield. Last year no one who was present on the occasion can have forgotten the venerable Frenchman who accepted from my hands this gift of the Queen or the striking address in which he testified his appreciation of the honour—an address which, as we were subsequently informed, had been perused with no ordinary interest by Her Majesty. It is gratifying to know that the prolonged and active life of M. César Daly is still absorbed in the study of the art to which he has dedicated his powers, and ennobling to find octogenarian energy of such exceptional vigour devoted to the pursuit of a cause so commendable, so irreproachable, and so well calculated to benefit society. I have thus experienced the happiness of presenting this royal gift to an Englishman and

to a foreigner, but when I regard the proceedings in which we are now engaged I feel some difficulty in deciding what is the nationality of the recipient of the Royal Gold Medal in 1893, for the distinguished architect whom it is at once our pride and our privilege to be permitted to honour can scarcely be defined either as an Englishman or as a foreigner. He is no doubt an Englishman in the sense that he speaks the Anglo-Saxon language, but on the other hand he is not an Englishman in the sense that he was born and finds a domicile beyond the limits of the British empire. He is no doubt a foreigner in the sense that the scene in which he has achieved celebrity is not British soil, but on the other hand he is not a foreigner in the sense that his nationality is so intimately linked to our own that we scarcely regard it as separate or distinct. What shall I say, then? If he is not an Englishman, and if he is not a foreigner, there is but one word in our vocabulary that will truly describe his nationality—he is an American. Thus, whatever interest may have been associated with any or all of the forty-five eminent men on whom this medal has been conferred, it is obvious that the present occasion has no parallel, and is indeed unique; for we are about to do honour to a citizen of the great Western Republic, one whose name we are proud to enrol as one of our Royal Gold Medallists, not only on account of high personal and professional merit, but also because he is the first American whose name will appear in that roll-call of illustrious artists. That the selection should this year have fallen on one who has designed the principal building in the great Columbian exposition which attracts the world's sightseers to Chicago at the present moment, and which will hereafter associate the name of America with the most wondrous development that international exhibitions have ever reached, or are ever likely to attain, is, to say the least, a singularly fortuitous coincidence. In honouring Mr. Hunt, in recognition of his eminence and of his works as an architect, we rejoice that we are thus able to pay a graceful tribute to the United States in the person of one of her most distinguished sons.

Mr. Richard Morris Hunt, born in Brattleboro, State of Vermont, in 1828, comes of an old New England family, and is the son of the late Honourable Jonathan Hunt, member of Congress. On his father's death his mother removed to New Haven, and his education was commenced at French's school and continued at the Boston High School and Latin School. In 1843—at the age, therefore, of fifteen—he accompanied his family to Europe and entered a school at Geneva, commencing the study of architecture with Alphonse Darier. From Geneva he went to Paris and studied under Hector Lefuel, entering the Ecole des Beaux-Arts in 1845. On leaving the Ecole he travelled through Europe, Asia Minor and Egypt, and on his return to Paris in 1854 he received from the French Government the appointment of "Inspecteur aux Travaux" on the new buildings uniting the Tuileries to the Louvre. His master, Lefuel, having, during his absence, succeeded Visconti as architect, he was put in charge of the Pavillon de la Bibliothèque, opposite the Palais Royal, and had the honour of making, under Lefuel, all the studies and full-size drawings of that pavillon.

Having thus stored his mind with a knowledge of some of the celebrated monuments of the Old World and acquired practical experience, he returned to America in 1855, at the age of twenty-seven, and spent about six months in assisting the late Thomas U. Walter at the capitol of Washington. He then, at New York, commenced the practice of his profession, to which he has enthusiastically devoted his powers throughout an exceptionally busy and distinguished career.

Shortly afterwards he took an active and a prominent part in founding the American Institute of Architects, a body which now has chapters in various parts of the United States. He succeeded R. M. Upjohn and Thomas U. Walter as president, and subsequently was elected President of the Institute under its reorganised constitution. He was also for several years President of the New York chapter of the American Institute.

Soon after commencing his career in New York Mr. Hunt opened an architectural atelier for students on the French system, thus demonstrating in a practical form the native energy of his mind and the influence which his European studies had exercised. Many of the leading architects in America to-day, such men as Professor William R. Ware, George B. Post, Frank Furness, Henry van Brunt, Charles Gambrill and others, were students in this atelier, and it is natural that Mr. Hunt should feel proud of the eminent position they have achieved, for who will venture to say how much they owe to the teaching and inspiration they received in the first American atelier?

In 1867 Mr. Hunt served as a member of the Fine Arts Jury at the International Exhibition in Paris, in 1876 he held the same office at the Centennial Exhibition in Philadelphia, and in this present year of grace he has served as a member of the Fine Arts Jury of Selection and as President of the Board of Architects at the World's Columbian exhibition at Chicago.

In 1882 Mr. Hunt received from the French Government the decoration of the Legion of Honour, and was elected a

Corresponding Member of the Institut de France in the following year. He is an Honorary Member of the Société Centrale des Architectes Français, and of the Architects and Engineers' Society of Vienna, and an Academician of St. Luke at Rome. He has been highly honoured by Harvard University, the oldest and foremost seat of learning in America, which conferred on him the degree of LL.D., the first ever conferred by that university on an artist. Lastly, we have ourselves the honour of claiming Mr. Hunt as one of our Honorary Corresponding Members, and in anticipation of the more intimate relationship we are now about to assume, it may not be uninteresting to note the views which have been expressed on behalf of both the United States of America and France with reference to Mr. Hunt's acceptance of the honour which we are now permitted to be the medium of conferring on him.

From France the President of the Société Centrale des Architectes Français thus addresses Mr. Hunt:—

Paris: le 8 avril, 1893.

Mon cher et honoré Confrère,—Le Bureau et le Conseil de la Société centrale des Architectes français m'ont chargé de vous adresser les vives félicitations de notre Société pour l'honneur si justement mérité que vient de vous conférer l'Institut royal des Architectes britanniques, en vous octroyant, cette année, la grande médaille d'or de la Reine d'Angleterre.

C'est, croyez-le bien, une profonde satisfaction pour nous de voir attribuer cette haute et rare distinction à un architecte que beaucoup d'entr'e nous ont connu, estimé et aimé comme condisciple à l'Ecole des Beaux-Arts à Paris et comme collaborateur d'un de nos maîtres les plus éminents, M. Lefuel.

Nous aimons à penser que c'est un peu l'architecture française qui vient d'être honorée en votre personne en même temps que l'architecture américaine.

En tout cas, c'est de grand cœur que je me fais l'interprète de félicitations, auxquelles je m'associe pleinement, envers un membre correspondant de la Société centrale des Architectes français, envers un artiste à qui son talent et ses mérites ont valu le titre de correspondant de l'Académie des Beaux-Arts.

Veuillez agréer, mon cher et honoré confrère, l'assurance de mes meilleurs sentiments confraternels.

Le Président de la Société des Architectes français, Membre de l'Institut,

H. DAUMET.

In reply to an invitation to be present on this occasion, His Excellency the American Ambassador in London has addressed to the Secretary of the Royal Institute the following letter:—

Embassy of the United States, London:

June 14, 1893.

Sir,—Mr. Henry White, secretary of this Embassy, has acquainted me with the contents of your note to him of the 13th instant, in which, on behalf of the President and Council of the Royal Institute of British Architects, an expression of their desire is made that, as the Ambassador of the United States, I should be present on the occasion of the presentation of Her Majesty's Gold Medal for Architecture to Mr. Richard M. Hunt, of New York, in recognition of his executed works as an architect.

Nothing would be more gratifying to me personally—nothing more gratifying to the people of the United States—than my presence as their representative on an occasion so honourable and of such just distinction to a citizen so eminent in the great profession he has so long adorned.

Of Mr. Hunt's professional skill as an architect, sustained as it is by his personal merits and high character, there is in his own country a consensus of opinion; and to know that his renown has surpassed the limits of his native land, and has met the well-earned applause of the most competent critics of other nations, is a just cause of national pride, which I am sure will be felt when the announcement of the proposed honour to him shall become publicly known in America.

Under instructions of my Government my first duty in Great Britain is the presentation of my credential letter to Her Majesty, and until this shall have been accomplished it would seem proper that I abstain from other acts of an official nature. Therefore I have asked Mr. Henry White, the secretary of this Embassy, to be present as a representative of the Government and people to whom honour is paid when it is bestowed so deservedly upon their distinguished compatriot Mr. Hunt; and I am, sir, most respectfully, your obedient servant,

T. F. BAYARD.

I have referred to these communications because it is pleasant to be thus assured that he whom we delight to honour is held in equally high regard by his compatriots alike in the United States and in France. To describe in detail the work of an architect whose practice has been so extensive and varied entails considerable labour, and it would seem to be superfluous in the present case. Mr. Hunt's principal works, most of which are of Classical design, are characterised by both vigour and purity in composition; and many of them are well known to some here this evening.

I have said enough to demonstrate, were demonstration required, that the recommendation of the name of Mr. Richard Morris Hunt, which we humbly submitted to Her Majesty, is not merely justified by the meritorious works and by the distinguished career of the man, but has been confirmed by the unanimous testimony of those who are best able to judge of his qualifications, both in Europe and in America.

Mr. Hunt, in presenting to you this Gold Medal, the gift of Her Most Gracious Majesty Queen Victoria, I hand you what is the typical embodiment of the recognition by British architects of your distinguished and honourable career, and of the high architectural merit of your works. The fact that you have travelled some thousands of miles in order that you might personally receive this medal may be accepted as sufficient evidence of the high estimation in which you rightly regard the honour. It is indeed the highest which we are graciously permitted to offer to the most illustrious architects of the world, and we indulge the hope that our American brethren will recognise in this royal gift, which we are privileged to present to their most eminent representative, the embodiment of the hearty goodwill, the sincere respect and the ardent admiration with which they are regarded by the architects of the Old World.

Mr. HUNT said it was useless to express how embarrassed he was, for nothing that he could say would fully represent his feelings of gratification, gratitude and thankfulness to the Institute. He had had many honours conferred on him, but the gift of the Queen had a peculiar charm, and being presented by his own *confrères* he accepted it and was proud of it for himself, and also proud of it for his country. In accepting it he did not do so personally, but for the whole profession in America, for so the Americans accepted it, and he also accepted it as a compliment to France. Referring to the works between the Tuileries and the Louvre begun by Visconti, he said Lefuel twice refused to undertake the work, because the architecture of France would not be represented. At last he consented, but on his own conditions as to style and other details. After describing how he and Lefuel conducted the work which had already been commenced, he said he thought he had been too much favoured and had received too many compliments, though it was true he had been forty-nine years at work. Remarking that America was celebrating its fourth centenary, he spoke of the exhibition. Chicago had obtained the privilege of holding it though other States had wished for the honour. He alluded to his work on the buildings there and how he had with the Committee of which he was chairman settled on a style that should be suitably monumental for the occasion. Iron, glass and tile were best suited for exhibition buildings, but the problem how to adapt them in a proper monumental fashion had never been solved. For the first time in America had they introduced painting and sculpture for monumental purposes in a building. Mr. Hunt concluded by a hit at the anomaly of the supervising architect having so much of the building work. The list of the supervising architect a few weeks ago had on it over 300 buildings for erection, and every year millions of dollars were spent on buildings. They had been trying to break up that system.

Mr. HENRY WHITE, secretary of the American Embassy, said it would be superfluous and presumptuous to refer to Mr. Hunt's works, whose name was associated with progress and beauty in architecture. The compliment to Mr. Hunt could only strengthen the chain of interest and sympathy that had grown on him during his nine years in England.

Baron VON GEYMÜLLER spoke on behalf of the Academy of Fine Arts, France.

M. PAUL SEDILLE excused himself for speaking in French. He said French architects were proud of their *confrère* Mr. Hunt, who had transported across the Atlantic the delicacy of their art. Art had no limit as to country. Art belonged to all ages. He admired the English works, an admiration which was shared in by the bulk of his compatriots. What was suitable in England might not be suitable in France, and *vice versa*.

The formal business then terminated, and the assembly repaired to the east gallery to listen to the band.

GEOMETRY IN DESIGN.*

IN presenting this Society with some illustrations of geometry in design, the author has given to the word "design" a somewhat wide meaning, and yet a meaning which, he ventures to think, it may legitimately bear. For he conceives that the process of designing involves the determination of the plan or section; the composition and outline of the elevation; the form—whether determined from scientific or from aesthetic principles, or from both—of the various structural details, before we come to the more limited question of ornament. The author ventures to think that, regarding the word "design" in this, its accurate sense, he has kept within the limits which nomenclature imposes.

In considering this subject one could not but remember a remarkable canon of a remarkable authority, who says:—"I would insist especially on the fact that all most lovely forms are directly taken from natural objects; because I would fain

* A paper read by Mr. H. A. Saunders, M.A., at the meeting of the Society of Architects on Tuesday, Mr. A. E. Stoner, member of council, presiding.

be allowed to assume also the converse of this, namely, that forms which are not taken from natural objects must be ugly." And yet there is a peculiar interest and pleasure; and therefore, it may be, also beauty, in geometrical design arising from its being an adaptation of forms which have existed from an indefinite period, whose properties are necessary adjuncts of space, or at least of such space as we can conceive of, and of which, ultimately, we can justly say that they have not been invented but discovered. Some of them, it is true, appeal to us because of their familiarity. Mr. Ruskin himself speaks of the circular arch as suggestive of the expanse of heaven, and of the pointed as reminiscent of the natural shape of the leaf. But there appear to be others whose beauty depends on their subtlety, as, for example, the delicate curves of Greek art; others again which, like the diapers and interlacings of Moorish and Saracenic art, delight us by their wonderful ingenuity; while other geometrical forms, while not presenting the same complexity are, to say the least, highly recommended to our notice by their associations or symbolical interest.

There are, of course, many forms which combine the natural in a greater or less degree with the geometrical, and to which, perhaps, the title of "geometrised natural" might be assigned. The earliest examples of such class, or, indeed, of geometrical design in any sense, are probably to be found in the splendid range of temples, tombs and monuments on the banks of the Nile. For although among the Egyptian ruins the natural types from which the form is evolved are sufficiently evident, yet in many cases careful investigation has disclosed a more or less strict geometric law, to which the design has been conformed, and the discovery of which has revealed to us a degree of scientific knowledge among the Egyptians of 1,500 years and more before Christ which was probably never exceeded after the Greek era until as many years of the Christian dispensation had elapsed.

We have two forms of papyrus column in which the stem appears in the shaft and the flower or bud in the capital, and which, on close examination, speak volumes for the knowledge and accuracy of the Egyptian designer. These columns are derived from the single papyrus stem. Though they are circular (and the papyrus stem, as we have seen, of the form known architecturally as the spherical triangle), yet they retain, it is believed, in almost every instance vertical lines on the shaft, the trace of which on any horizontal circular section gives the angular points of the inscribed equilateral triangle.

This alone would be sufficient for identification if the general form were not so close a copy of the natural object. Yet by measurement and investigation it becomes soon apparent how completely "geometrised" the form has become in the hands of the architect.

And here, before proceeding further, the author will show some slides illustrative of some of the forms and properties of the conic sections.

Turning now again to our papyrus pillar of the species in which the capital represents the unopened bud, and which is well shown on the left of the view of the east gate of Memnonium, we have first to notice that the dimensions of the parts are found to be simple fractions of the height of the column, so that the height regulates the proportions of the whole in a manner not, indeed, destructive of individual treatment, though originality certainly received but scant courtesy in ancient Egypt, but sufficient, at least, to indicate generally accepted rules of simple commensurability. In an instance of this class, taken from the temple of Medinet Habou, on the west bank of the Nile, at Thebes:—

Width of abacus = one-fifth of the height of column = 6'094 feet.

Width of abacus or height of column = 6'094 feet.

$\frac{10}{10}$ or $\frac{50}{50}$ Of these latter parts, each = 6'094 feet (fiftieths).

4 parts = height of base = height of abacus = 2'437 feet.

12½ parts = height of capital = 12½ = 7'6175.

15 parts = width of capital = 15 = 9'14.

But, in addition, while the base is in many cases a zone of a sphere, or of a sort of "millstone shape," and the capital is apparently formed by superposing a segment of a cone on a portion whose vertical section gives a circular trace, the profile of the shaft has been shown to be a hyperbola, whose vertex is at the junction of the shaft and the base. But, more than this, the foot of the ordinate of the point where the profile of the shaft meets the capital is distant from the vertex ten times the length of the semi-transverse axis of the curve. And not only this, but remembering, of course, that a vertical section through the axis would show two profiles, the ordinate to the hyperbola through the same point appears to cut the section of the capital (on the same side) in the point where the circular curve in the section of the lower part of the capital (or base of the unopened bud) runs into the generating line of the cone by which the upper part of the bud is represented.

This evidence of careful design and mathematical knowledge on the part of architects who flourished at least 2,500 years ago is a matter of singular interest among the numerous

examples of a civilisation which was already at its zenith when Abraham went down into Egypt, and when Moses was educated "in all the learning of the Egyptians."

The species in which the capital conventionally represents the blown flower has similar geometric properties, and is of particularly graceful contour. These are well shown in the view of the Great Hall at Karnak. They varied in size, the inner chambers of Egyptian temples being less lofty than the outer; but it may be of interest, as helping us to realise the scale on which much of the Egyptian work was produced, to recall Kenrick's observation, that "it would require six men with extended arms to embrace the circumference" of some of the larger columns in this temple.

The Egyptian entablatures were simplicity itself compared with the complicated suite of mouldings which crowned the Greek temple. They consisted in some cases of a plane corona, a soffit of hyperbolic section, a moulding of elliptical profile and a plane architrave. The hyperbolic curve of the soffit is here of smaller eccentricity, and with its transverse axis at right angles to the line joining the edge of the corona to the angle of the elliptic moulding, which latter also supplies proof that the Egyptians were acquainted with another conic section.

Segments of circles have been found in the roofs of various sepulchral chambers, and in one case at least an example of a false ellipse struck by circular arcs drawn from three centres.

But one of the most interesting discoveries in connection with the mathematical planning of a sepulchral chamber has relation to the tomb of one of the governors of Southern Egypt in a sepulchral grotto at Beni-Hassan, between Minieh and Thebes. In the plans of most of the tombs some simple proportion connects the length, breadth and height. For instance, in the tomb of Sethos I., discovered by Belzoni, the height and breadth are each 11-18ths of the length, and the author believes that the symbolical form of the double square occurs not infrequently. But in this particular instance commensurability has been departed from in order to give to the length, breadth and height the somewhat unusual ratios of $\sqrt{5} + 1 : 2 : 2$. Unusual at first sight, and yet when stated in this form recalling the geometrical construction for the size of 18 deg., and thence the process for dividing a line in extreme and mean ratio. In fact the length, breadth and height are arranged in such a way that the length is equal to the sum of the breadth and the height, and at the same time the rectangle contained by the length and the height is equal to the square on the breadth. Here then we have an example of the knowledge of a proposition of Euclid probably twelve centuries or more before Euclid's time, and a glimpse of the antiquity even in his days of the discoveries which he embodied in his immortal compilation.

The forms of Egyptian architecture and ornament which were adopted and adapted by the Greeks are many. Egyptian frets are in many instances almost identical with the familiar Greek pattern. The more or less irregular star pictures on blue grounds in the roofs of Egyptian tombs are reproduced with artistic developments in the square panels of the Greek temples—notably of the Erechtheum. The peripteral arrangement, too, of the columns, though the author believes it has been regarded as essentially Greek, yet seems perhaps to have had a prototype in the columned ways surrounding many of the Egyptian temples, though in these cases the shafts sprung from or were enclosed by a wall surrounding the building, as, for example, in the case of the small temple at Philæ, known familiarly as Pharaoh's bed, and in another instance on the adjacent island of Elephantina. But if this be doubtful the fluted column, supposed by some to have been suggested by the striated bark of the unshaped posts supporting the early Greek hut, has what appear to be undoubted prototypes among the Egyptian ruins. Of these the well-known examples of proto-Doric columns at the entrances to grottoes at Beni-Hassan already referred to are among the most interesting. But we have not the flute. The capital, with its projecting square abacus and simple echinus is distinctly suggestive of the Doric order, and though the eight (or in some cases sixteen) faces of the shaft are not fluted, but merely plane (so that the section is a regular polygon of eight or sixteen sides), the general effect points to them as the original of the columns of which the Parthenon supplies the most perfectly developed specimens. These columns are of great antiquity, and are usually referred to a period of about 2000 B.C.

The author has also been able to secure a view of columns of remarkable section in which the flute actually occurs. These are obtained by fluting all the column with the exception of four vertical bands, symmetrically placed, on which the original curved surface of the column remains. So far as the author has been able to discover, the sections of the flutes are of segments of circles. In number they vary, specimens at Thebes exhibiting six and three in each group. To those at Thebes are assigned the date 1600 B.C. The example shown is from Kalabsee, and the ancient Talmeo, in Nubia.

During what period the Greeks were more or less subject to Egyptian influences it would be impossible to say. In the Mycenaean sepulchres Dr. Schliemann discovered bronze swords ornamented with the papyrus, bearing great resemblance to Egyptian work, and more particularly to a dagger discovered in the coffin of one of the queens of the Eighteenth Dynasty. We know from Herodotus that the Greeks derived many of their notions of geography—such as they were—from the Egyptian priests; and it seems extremely probable that they inherited a richer legacy of mathematical knowledge from the same source. Further investigations may discover additional proofs of Egyptian knowledge, but as far as we know at present it would seem that the torch handed down to the Greeks by the Egyptians burnt brighter in the hands of its new bearers.

Returning to the subject of the Egyptian temple for a moment, in order that one may point out the central line of approach entered through the massive Pylon, and marked by an avenue of sphinxes and obelisks by which it was reached.

With this we may compare the Greek plan as illustrated by the approach to the Acropolis. The Athenian approached this storehouse of his country's artistic—and scientific—wealth by a winding road which led him to the impressive Propylæa, suggested it may well be by the Egyptian Pylon. Passing through this stately entrance he reached the summit of the sacred rock which overhung his city, and was led by a road marked by statues and monuments to a point whence he viewed from below and angularly the most imposing—if not in all respects the most perfect—of the shrines of his deities, the temple sacred to the protectress of the commonwealth—Athene.

Now the Athenian architect built with the intention, not that the building he designed should conform to his own notions of beauty and symmetry, but that the effect it produced on the observer should be the embodiment of his conceptions. His measurements and proportions are embodied in the stones of the building; his ideas can only have been thoroughly and exactly realised by the observer gifted with the capacity of appreciating to the full what was delineated on his own picture plane.

So, although the subtle beauty of the columns and the sculptures of the pediment must have first struck the eye, we will pause for a moment to consider a point apparently of small importance, but not so small, evidently, as to escape the care of the Greek artist in his endeavours to attain perfection.

We have sufficient historical testimony to the fact that to the Greek eye a prolonged straight line gave the impression, not of a straight line, but of a curve hollowed out towards the middle. But if we had not known this we might have been puzzled by what has been revealed to us by the careful measurements to which the Parthenon, the Theseum, and other porticoes have been subjected. In the 101 feet of the stylobate on the east front of the Parthenon, the centre of the step rises to a height of nearly $2\frac{3}{4}$ inches, while on the return side in 228 feet the rise is $4\frac{1}{4}$ inches as nearly as possible; and by comparison of intermediate ordinates it has been shown that the curves of the steps are probably arcs of circles. This being assumed, the radius of the circle of which the line of the step is an arc is found to be about a hundred yards more than a mile, while the radius of the corresponding curve in the Temple of Theseus is about two miles and a half. Knowing what we do of the history of this subject, we are yet at a loss to account for the exact principles on which the form and curvature of this line were determined, and when we consider that the rise is equivalent to something less than 1 in 200, it seems remarkable that such nicety of curvature should have been appreciated. Yet the occurrence of a similar optical correction in the Theseum, the Temple of Jupiter Olympus, and elsewhere, except in the case of very small structures, shows that it was an essential geometrical principle of design.

Very analogous to this is the question of the entasis of the column. We may note, in passing, that the extreme or angular columns were designed from 1-40th to 1-50th larger in average diameter than the rest, in order that the play of light around them might not make them appear more slender than their companions. So, too, that the columns might not appear of concave or, as it were, dice-box profile, the centre of the shaft had a greater diameter than it should have had according to the simple proportion which would have determined it if the form had been that of a frustum of a cone. What was the law which governed this entasis is a matter which has given rise to much discussion, and been decided in different ways by different authorities.

The curves which appear to approach most closely to the actual curve of the shaft, so far as can be determined, are hyperbolas. But the extreme delicacy of the changes in curvature, and difficulties of measurement, make the question one of great intricacy. The results obtained seem to point to the curve of profile, in the case of the Doric column of the

Parthenon, being an arc of a hyperbola, whose vertex, if the curve were prolonged, would occur at a distance of two diameters, measured at the base of the column below the level of the upper step. The rectangular axes of the curve are vertical and horizontal; the eccentricity is calculated to be 30·1, and the radius of curvature of the hyperbolic section at the base of the column has been determined to be five times the length of the building, or over 1,200 feet. Practically, in fact, the lower part of the profile may be taken to be a straight line for some little distance up the shaft, but not a straight line parallel to the axes of the column, but inclined inwards at an angle which corresponds roughly to a rise of 1 in 200.

In this connection we have a very interesting distinction between the columns of the Parthenon and the Ionic columns of the Erechtheum and the Propylæa. In these latter cases there appears to be no doubt about the nature of the curve. The vertex, or point of maximum curvature, occurs in these cases as nearly as possible in the centre of the shaft. If it were exactly in the centre the tangent at the vertex would be, of course, parallel to the chord of the whole arc employed. This is nearly the case, and as a consequence of the diminution of the diameter of the column the axes are no longer vertical and horizontal as in the former case.

(To be continued.)

BATH PUMP-ROOM EXTENSION SCHEME.

AT the meeting of the Bath Town Council, as reported by the *Argus*, the following report was read from the Baths and Pump-room Committee:—

On March 8, 1892, the Council adopted a report of your committee sketching the general features of proposed increased accommodation in connection with the Grand Pump-room, and authorised an application to the Local Government Board for their sanction to a loan of 6,000*l.* for the purchase of Nos. 2, 3 and 4, Abbey Churchyard. A memorial was presented to the Local Government Board, and an inquiry was held by Mr. S. J. Smith, C.E., one of their inspectors, on June 14, 1892, and on September 27, 1892, the Town Clerk reported to the Council that the sanction had been obtained. On November 9, 1892, the Council, upon the recommendation of your committee, accepted the tender of Messrs. Jacob Long & Sons for excavating the site down to the level of the Schola of the Roman Bath, amounting to 550*l.* The excavation being now complete, the time has arrived for taking the next step for the accomplishment of the scheme, and your committee recommend that the surveyor of works to the Corporation (Major Davis) be instructed to prepare and submit to the Council a plan and design for the utilisation of the site adjoining the Roman baths.

Mr. Radway (chairman of the Baths Committee) said it had been his custom to move the adoption of reports from his committee, but on this occasion he was not in touch with the committee, and declined to vote when the report was brought before the committee, and carried by nine votes to eight. He reserved to himself the right of free expression, and called upon Mr. Ricketts to move the adoption of the report.

The Mayor suggested that the Town Clerk should read what was done under similar circumstances in connection with the municipal buildings scheme.

Mr. Ricketts submitted that the baths scheme was not on all fours with the municipal buildings.

The Town Clerk was about to carry out the Mayor's suggestion, when Mr. Ricketts proceeded with his remarks, but was interrupted by the Mayor, who urged upon the Council the importance of having before them what was done under similar circumstances in connection with the municipal buildings.

The Deputy Town Clerk (Mr. B. H. Watts) having read the minutes referred to, deciding that there should be competitive designs,

Mr. Ricketts rose to move the adoption of the report. He said because the Council adopted a certain course in regard to the municipal buildings they were not called upon to follow a similar course with reference to the baths. Having been called upon by the action of Mr. Radway to move the report, he would tell the Council how the whole thing came about. He was summoned to attend a special meeting of the Baths Committee, and found the table covered with plans which Major Davis had been requested to prepare. Questions were asked as to how Major Davis proposed to utilise one corner, the line he would bring the building out to, its height, &c. It occurred to him (Mr. Ricketts) that they were taking a false position by adopting such a scheme, and he inquired whether Major Davis had been instructed to prepare plans for the utilisation of the site. Learning he had not, he requested Major Davis to leave the room, and subsequently his resolution authorising Major Davis to prepare plans for the consideration of the Council was carried. That resolution was before them that day. It appeared to him (Mr. Ricketts) that the surveyor of works had considerable claims upon the Council with regard to the baths. It was a well-known fact

that Major Davis had for years paid very great attention to the baths, and it would not be denied that to his efforts to a great extent was due the present position of the baths. The baths were advertised as the most perfect in Europe, and that the Corporation had expended 40,000*l.* upon them. That advertisement was perfectly true, and to whom was this state of things attributable? Major Davis had by his energy brought the baths to their present state of efficiency, and they were indebted to him for the discovery of the Roman remains. He thought Major Davis ought to have the credit of that. A well-known member of the Council, referring to these baths, said for size, excellence and mechanical appliances they compared most favourably with any baths in Europe, and also, he went on to say, that the mechanical appliances were superior to any others. Taking it first as justice to the ratepayers, they had got a man who found them the finest baths in Europe by their own admission, and yet they wanted to go further and find some one who might possibly be able to give them anything finer than the finest. Then, with regard to the arrangements under which Major Davis was retained, he drew attention to clause 8 of his appointment, in which it was stated he should prepare all plans and specifications, for which he should receive no payment whatever, but for work over that he should receive payment. That clause, he said, although it possibly did not give Major Davis the carrying out of this work, certainly did give the idea that works over 1,000*l.* should be relegated to him. Under these circumstances he thought he had a claim; he had claims upon the Council on the ground of justice, on the ground of gratitude for what he had done for this city, and he thought under the circumstances that Council would do worse than adopt the resolution that he proposed. It was that the city surveyor of works should be called upon to prepare a plan and design, which he had ascertained would not exceed the cost of one hundred guineas provided nothing further was done with it, that it should be brought to the committee and then to the Council, who should do what they liked with it. He thought they might do this. That morning they had voted 178*l.* for an opinion; this was something more than an opinion. There was a very great diversity of opinion as to what they wanted, and he thought they could better settle what they wanted if they had the plan to look at and discuss. If he were Major Davis, and a competition was decided upon, he would not compete.

Alderman Commans seconded the adoption of the report. He considered that during the past twenty years no man had rendered the service to the city, the benefits to the baths and the usefulness to the waters that Major Davis had, and he thought the opposition was unjust, unkind and uncalled for. Was there any other man who had the knowledge of the requirements for internal arrangements that Major Davis had?

Alderman Gibbs rose to move an amendment, and at the outset denied Mr. Ricketts's statement that outsiders were of his opinion. The expressions of dissatisfaction that he had met with from all classes had been quite the other way. In his opinion Alderman Freeman had done a great deal more than Major Davis ever did in making the baths known. It seemed to have been lost sight of by those who spoke of Major Davis as the originator of the appliances, &c., that it was the late Dr. Burne, father of Mr. Holland Burne, who first pointed out that the drinking of the waters and the bathing constituted only a portion of the proper treatment, and he particularly referred to the mechanical treatment with appliances adopted at places on the Continent. There were a great many heads of objection to Major Davis. In the first place his dilatoriness. They rarely had things brought up in time to give them full and fair consideration; they were mostly brought up at the last moment. He ventured to say that no man of business would be satisfied to place such an important work as this in the hands of anyone who had discharged his duty in the perfunctory manner in which Major Davis had discharged his. Alderman Gibbs was proceeding in this strain, when

Mr. Lewis rose to a point of order. It seemed to him, he said, to be a personal attack upon Major Davis.

Alderman Gibbs explained that the other speakers had spoken of Major Davis in a personal sense, and he was giving an opinion from another point of view.

Mr. Ricketts said Alderman Gibbs had often told them not to speak of a question of order. He had stopped him (the speaker) more than once.

Mr. Lewis thought it was unfair and cruel.

The Mayor said: So far as I could catch Alderman Gibbs's observations they were to this tendency, that whereas the mover and seconder have shown why he should be employed, he has shown why he should not be entrusted to do this work.

Alderman Gibbs proceeding, said there were a great many points, but he would not trouble the Council further. Major Davis's dilatoriness, his absence at times when he was wanted, his disregard of the directions of the Council—any gentleman who authorised the erection of the screen for the Pump-room, let him say so. It was notorious that he did it out of his own head—that it was never authorised. He not only disregarded

the committee but he defied them. Having dealt with Major Davis's conduct in other matters, Alderman Gibbs moved as an amendment, "That advertisements be issued as in the case of the plans for the new municipal buildings, inviting architects to send into the Town Clerk competitive plans for the work which might be arranged by the Town Council on the site proposed by the Baths Committee, such works to be carried out under the superintendence and conduct of the successful candidates on the usual terms of remuneration, and that quantities be taken out by a disinterested and competent person from London, and that Mr. Brydon be asked to assist the Council in the matter."

There was no seconder to the amendment.

Mr. Radway said he deprecated in the strongest manner any personal allusion either to the ability or the want of ability, if such existed, of Major Davis. He wanted the question to be dealt with on a broad and businesslike principle. He gave to Major Davis much of the credit that had been assigned to him, but to say that to Major Davis the present prosperity of the city was to be attributed was saying something that was not absolutely true. He asked for a dispassionate consideration of the question. They were about to enter upon an important epoch in the city's buildings, and they were hopeful that it would bring people to Bath and enhance its prosperity. If they asked him to consent to shut Major Davis out of the competition for designs, he answered he was not with them, but he asserted that Major Davis did not possess the whole of the architectural knowledge of England, neither could he claim to be a specialist. His amendment was that the Council advertise for premiated designs, offering premiums of 100*l.*, 75*l.* and 50*l.*, and that the Society of British Architects be asked to nominate a gentleman as assessor. He asked that Major Davis should not be debarred from competing. If his friends said he was afraid to compete, it was the strongest argument that they must go further afield. He was asking for a simple matter, that the brains of England should be at their disposal. They might have a dozen or less designs sent in, but when they had them, then, with the aid of a competent assessor, they would certainly get the best money's worth. Mr. Radway was proceeding to speak of Major Davis's share in the competition, when

Mr. Ricketts said Major Davis would not compete.

Mr. Radway thereupon asked whether they were so left to the mercy of one of their officers that he said he would not compete, but preferred to run the gauntlet and force upon the Council his views and his views only, whether they were to the interest of the city or not? He did not believe that was the spirit in which Major Davis intended to act, but it strengthened his (Mr. Radway's) hands in asking for a competition of architects.

Alderman Jolly seconded the amendment, and asked what would be the result of adopting such a proposal as Mr. Ricketts had made, viz. that Major Davis should have the entire control of the designs? Who would advise the committee in arriving at a decision that required technical assistance? Major Davis was the legitimate adviser of the Baths Committee, and he (Alderman Jolly) regretted to say he had received a note from him that morning in which he absolutely declined to act as assessor.

Mr. Ricketts asked for the letter to be read.

Alderman Jolly said it was a private letter. He had a private conversation with Major Davis the previous day, and that morning he received a note from him urging his claims for appointment.

Mr. Ricketts: Does not he ask you to read it to the Council?

Alderman Jolly answered in the affirmative, adding, however, that it was a private letter. He asked the Council to act as they did in the case of the municipal buildings, feeling sure it would be satisfactory at all events to those who had any responsibility in the matter.

Alderman Chaffin supported Mr. Ricketts's proposal, and claimed that Major Davis was capable of fulfilling all requirements in this matter. In the municipal buildings there was a freedom of design; in this case the architect's hands would be tied, and the elevation was bound to be a continuation of the present Pump-room, the architecture of which was elegant, beautiful and Classical.

Mr. Sturges spoke in favour of Mr. Radway's amendment.

Mr. Moore said there could be no harm done in asking Major Davis to draw up plans for utilising the site at a cost of about 100 guineas. The Council need not accept the plan, but they would have the benefit of Major Davis's experience. He (Mr. Moore) was quite sure he would not compete, and he did not blame him for taking this course.

Mr. Chivers asked to be made acquainted with the terms of agreement between the Corporation and Major Davis.

The Town Clerk produced the agreement, which bore out what Mr. Ricketts had said on this point.

Mr. Chivers said according to this they were not obliged to give Major Davis work above 1,000*l.* He himself could see

how valuable it would be to go further afield and get the best experience they could.

Mr. Eaton Young said the Council were not capable of deciding whether a plan and design by Major Davis were the best for the purpose. The Council could not arrogate to themselves to be censors of the canons of architecture, and this made an assessor absolutely necessary. Anything like the course proposed would simply be throwing away 100 guineas.

The Mayor said the Council were aware that it had not been his custom to give a vote on matters on which there was likely to be a sharp division, but he could not refrain from doing so that day because he thought a very important principle was at stake, a principle which had been deliberately adopted by that Council, and acted upon with considerable advantage. The principle referred to was that of throwing open the competition for the plans, and he pointed out how successfully it acted in connection with the new municipal buildings. It had been urged, he continued, that they ought to throw aside this principle because Major Davis had done so much for the baths, but was Major Davis the architect when the first new baths were erected? Was it not to the prosperity of these baths that success was due? He pointed out that Major Davis was not the architect then, while the second erection for which he was responsible was, to his mind, full of faults. It was anything but an ornament to the city. They could not, he considered, have full confidence in Major Davis. If he had the sole control of this thing, if he brought forward a plan without any competition, then, he felt, they would be at his mercy, and he appealed to them whether they could sufficiently trust Major Davis in a matter so important.

Mr. Radway wished to explain that he had no feeling against Major Davis, and he had during the last few hours done everything to get Major Davis to come into the scheme and act as assessor. He now deliberately and positively said he would not accept that position.

Mr. Lewis asked whether Major Davis did not get the first premium when the baths adjoining the hotel were built.

It was stated that this was the case, but that the second design was carried out by the committee.

Mr. Radway said Mr. Lewis was quite right. Major Davis got the first prize, but the cost was so great they could not consider it.

Mr. Ricketts, replying, urged that it was due to Major Davis that a chance should be given him of perfecting the work which he had commenced.

The amendment was then put to the meeting, and carried by a majority of nine votes, the original motion being lost.

THE LATE JAMES MACLAREN.

MR. JAMES MACLAREN, the respected head of the well-known firm of Messrs. James Maclaren & Sons, architects, Bank Street, Dundee, died suddenly and under peculiar circumstances, the *Dundee Advertiser* of the 19th says, on Friday evening, at Kingskettle, Fife. Mr. Maclaren was present at a meeting in the Public Hall there, held under the auspices of the East Fife Liberal Organisation, and had not long resumed his seat, after speaking in support of a motion expressive of continued confidence in Her Majesty's Government and in Mr. Asquith, when he was seized with sudden illness. He was immediately removed to the anteroom of the hall, where everything possible was done to render him relief. All efforts, however, proved useless, and Mr. Maclaren expired in the course of a few minutes. Meantime, Drs. Butters and Laidlaw, Ladybank, were hastily summoned, but death had taken place before their arrival. The cause of death is thought to have been apoplexy or affection of the heart. The remains were removed to the house of Mr. Hogg, corn merchant, and subsequently conveyed to Ferrybank.

Mr. Maclaren was born in Dundee upwards of sixty years ago; he served his apprenticeship as an architect in the office of Mr. Smith, Reform Street, and thereafter was employed in succession with Mr. Johnstone, surveyor, Edinburgh, and Mr. David Bryce, R.S.A., Edinburgh. While engaged in the capital he was successful in gaining the Soane Prize Medallion, one of the most highly coveted of architectural honours, his design being one suitable for public baths. At an early age he started business, first in partnership with his brother William and afterwards on his own account, in Reform Street, Dundee, and during a long career has been very successful. Among his first architectural works were the designs for the Forfar Prison and the Peel Monument, Forfar. He was the architect for many buildings, both public and private, in Dundee, and, besides, he has erected buildings in all parts of Scotland. It may be mentioned that, among many others, he designed Lamb's Hotel, the offices of the Northern Assurance Company, the Messrs. Cox, Messrs. Don Brothers, Buist & Co., Calcutta Buildings, and Russell Chapel, Dundee; Lochee U.P. Church; Ryehill U.P. Church, Dundee; Queen Street U.P. Church, Broughty Ferry; the Congregational Church, Broughty Ferry;

Barry Free Church; Arbroath Public Hall; Balthayock House, Ashludie House, Clement Park, Convalescent Home (Barnhill), &c. A number of years ago Mr. Maclaren took up his residence at Ferrybank, Cupar Fife, and until the last was in the habit of coming daily to his place of business in Dundee. Despite the heavy exactions which his professional duties entailed, deceased found time to devote to furthering the interests of the county in which he had taken up his residence. He was an energetic county councillor for the Cupar Fife district, a J.P. of the county of Fife, and a member of the Lunacy Board. He was also a director of the Dundee Tramway Company since its commencement. During the whole of his life Mr. Maclaren evinced a strong taste for literary pursuits. He was editor of the *Building Chronicle*, an architectural journal published for a few years in Edinburgh, and of the *Angus Magazine*; he contributed leading articles to the columns of the *Northern Warder*; and he was editor of a republication of the "History of Dundee," written by Mr. James Thomson. He was, moreover, a frequent contributor upon architectural and agricultural subjects to the columns of local publications. His wide experience in railway business made him a much sought-after witness in arbitration cases, one of his latest appearances in that capacity being in the arbitration regarding the value of the Princes Street Gardens, Edinburgh. A man of the most genial and amiable disposition, Mr. Maclaren's sudden death will be mourned by a wide circle of friends. He leaves a widow and a grown-up family of sons and daughters. On Saturday deceased's family received a telegram from the Right Hon. H. H. Asquith, M.P., the home secretary, expressing sincere sympathy with them in their bereavement.

AMERICAN SILVERWORK.*

By H. TOWNSEND.

WHILE I felt not a little honoured by the request which was made to me a few weeks ago in this place, so redolent of the memories of men famous in art and letters, I felt more than usually diffident at the prospect of displaying my own shortcomings. However, I can only trust that the interest of the subject upon which I am to speak will outweigh the obvious unworthiness of the speaker. Indeed, if I succeed in carrying out my own intentions I shall appeal to you, not so much through my own inherent virtue of eloquence, as by being the means of a display of that virtue in others.

I am going to talk to you to-night about the silverwork of America, and it will not be, I take it, unfitting, before plunging *in medias res*, if I endeavour to briefly and succinctly lay before you the reasons which lead me to believe that the subject is one which entitles itself to be considered, even at such length as that at which I propose to treat it. Nothing is more apparent to anyone who, like myself, is addicted to the bad habit of staring in shop windows during the progress of his daily walks abroad, than that during the past ten years the employment of silver for the fashioning of all articles of household use or personal adornment has been largely on the increase. We are, in fact, living in a veritable "silver age."

Into the economic causes which have led to this vastly increased use of what we are accustomed to call a precious metal, this is not, I conceive it, the exact place nor am I a fitting person to inquire too closely. It is, however, apparent that the enormously increased output of silver from the newly discovered mines in Colorado, and other of the Pacific States of America, has played the chief part in the increased and increasing use of the metal in question. Since the discovery of America, for instance, silver has been produced to the value of no less than 14,000,000,000*l.*, of which only 3,000,000,000*l.* can be accounted for in existing coinage. This means that 11,000,000,000*l.* worth have either been used in the arts or practically lost to us. This enormously increased output, a great part of which has, as I have said, taken place in comparatively recent years, has naturally affected the intrinsic value of the metal, that is to say, its ratio to-day as compared with gold is only about half of what it was 500 years ago. The Roman ratio was, in the early days of the Republic, 10 of silver to 1 of gold, and subsequently increased to 12 to 1. The discovery by Spain of the mines of Potosi raised it to 13½ of silver to 1 of gold, at which it remained until the end of the seventeenth century, when the Portuguese practically governed the rate and raised it to 16 to 1. In the last few years it has approached more nearly to the ratio of 20 to 1 than has ever been known in the world's history. This relative cheapness of the metal has doubtless led to its more general introduction into our daily life. Be the cause what it may, however, the fact is certain that one cannot walk down Bond Street or Regent Street without seeing in every other shop window trinkets and nicknacks, personal ornaments and household utensils glittering in all the untarnished radiance of the white metal. Nor to silversmiths proper is this display

* A paper read in the Applied Art Section, May 30, and published in the *Journal of the Society of Arts*.

confined, but silver trifles, either for use or ornament, find a place in the windows of half a dozen other tradesmen and artificers. If this be the case in London, still more so is it in New York, where it would be difficult to find any article of daily use which one cannot procure either entirely fashioned of silver or in the adornment of which silver plays a most prominent part.

It is in articles of personal, and chiefly feminine, adornment that the new era of silverwork is chiefly noticeable in both countries, but especially so in America. Long swinging *châtelaines*, to hook on to the belt and go clattering along by the wearer's side, suspending silver-covered notebook, silver-mounted scissors, penknife, pincushion and so forth by silver chains; silver-mounted shoe button-hooks with chased and *repoussé*-work handles; writing-cases covered with plates of pierced silverwork; boxes of silver, for storing hairpins; round boxes, for the storage of the delusive face-powder and its feathery puff; quaint little receptacles for bon-bons; silver-handled brushes, silver-backed combs of tortoiseshell and mirrors backed with hammered silverwork; heavy silver filigree buckles and girdles; silver-handled paper-cutters, pen-holders, opera-glass holders, spectacle-cases, postage-stamp holders, pencil-cases, are displayed to catch a lady's fancy. For her husband and brothers the range is hardly less limited, and includes match-boxes of silver, cigarette and cigar cases, silver chests for cigarettes lined with cedar wood, hunting flasks, sovereign purses shaped like tiny watches, key-rings, shaving-soap cases, and so forth; while, for domestic uses, or for the purpose of entertainment, gilt-lined bon-bon trays, tiny little lamps, inkstands, cigar-ash trays, photograph frames of filigree mounted on velvet, silver gong stands and bells, card-trays, grape-holders, candlesticks and snuffers, and the usual array of teapots, cream-jugs and other articles classed under the generic title of "household plate," are to be found everywhere.

When, however, we come to consider more closely, and compare the actual manner in which this fashioning is effected in the two countries, we are struck at once by the wide difference of method, almost of principle, employed. Roughly speaking, we may say that the silverwork of England is a tradition, and that of America a discovery. The silversmith on this side of the water is hampered, I freely admit, in some directions. The mere fact of the standard fineness of his metal being rigorously guarded by law, while it has allowed the uninformed public to form a more sure estimate of the intrinsic value of his wares, has, in some mysterious way, lessened their artistic importance. For the last two hundred years at least some sort of check seems to have been placed in this country on the manufacture of silver, though it was not until the beginning of the fourteenth century, I believe, that any actual legislation upon the subject was put into operation. It was then decreed that a leopard's head should be stamped upon all sterling articles of gold and silver. In the year 1337 the Goldsmiths' Company of London was incorporated by Edward III., and this body until the present day have been wont to imprint their company mark, which is the same leopard's head to which I have referred, upon all articles of sterling silver which are manufactured in London. As you are doubtless all aware, there are six other Assay Offices in this country, namely, those of Birmingham, Chester, Sheffield, Edinburgh, Glasgow and Dublin. The hall-mark, which, by these offices, is stamped upon the articles of gold and silver, is evidence that these have been tested and the latter found conformable to the invariable standard of 92.5 per cent. of silver and 7.5 per cent. of alloy, or 11 oz. and 2 dwts. of fine silver to 18 dwts. of alloy. Although there is now no duty on gold or silver plate, the Hall-marking is practically compulsory, and not only this but foreign plate, although it comes in free of duty, must be marked before being placed on sale, and, in addition to the ordinary Hall-marks, have the letter "F" enclosed in an oval escutcheon. There is no manner of doubt but that this legal hampering of a trade or art which ought fairly to be as free as any other has seriously checked its development, at all events as regards what might have become many important branches of the main stem. At present, it is enough for me to point out that in America no such system prevails, and that to this fact is in some measure due the greater artistic freedom and originality which I hope to convince you is the distinguishing feature of the American silverworker. This craftsman, too, has been fortunate in being to a much greater extent free from the enveloping atmosphere of trade tradition, which has well nigh asphyxiated his English brother.

When the modern English silversmith is a staunch copyist and artistic forger, his skill, in a mechanical direction, enables him to produce work which is pleasing to the trained eye, and his reproductions of Queen Anne work and Italian and Dutch Renaissance—as in the fashionable tea-services on the one hand and in, for instance, the elaborate open-work *châtelaines* on the other—are, so far as copies can be so, satisfactory.

In the early years of the American colonies their silverwork, like the majority, if not the entirety of their luxuries, came to

them direct and by importation from the parent country. The old silverwork of Queen Anne and the early Georgian period is hunted for by the American collector in his own New England and Southern States, with all the keenness that is displayed in the same search by those misguided people on this side the Atlantic who are accustomed to pay more for the Hall-mark than for the article itself. In the early days of the independence of the States I believe that little silver plate of any importance was manufactured in the country itself, and when, in the early years of this century, the trade had become more or less established in New York, Philadelphia and Boston, it was to England, or perhaps more especially to France, that the craftsmen looked for their designs, which, I need hardly say, when the period is taken into consideration, were about as bad as bad could be. The impetus given to all domestic and, notably, all artistic manufacture in the United States by that extraordinarily epoch-making exhibition at Philadelphia in the centennial year of 1876, affected no less, indeed perhaps a little more than the others, the art of silverware manufacture.

The most strenuous note in the American artistic character is a reflex of that which dominates their political faith. It is that of freedom, or, as in connection with art matters the word might be spelled, originality. This, though at times it is apt in art as in politics to degenerate into license, is in the former happily restrained by that other and perhaps more hopeful American characteristic, appreciativeness. As in their architecture so in their subsidiary arts, the Americans seem unconsciously to assimilate, in a degree unknown to nations fettered by the bonds of tradition, all that is good in the art work of other peoples, and at the same time to impart to the conglomeration thus obtained a distinct flavour of their own individuality. In no branch is this more distinctly obvious than in their silverwork, though not a little of this virtue, for so I must consider it, is due to the life-labour of one man, whom I can only class, in the important influence he has exerted upon the American art of his generation, with that distinguished architect, Mr. H. H. Richardson, whose name, if not his work, is probably familiar to many here present. The man I refer to was curiously enough no silversmith himself; indeed, in the strictly technical sense of the word, he was not even an artist. I speak of the late Mr. Edward C. Moore, who was secretary to the Tiffany Company, to the kindness of whose London representative I am indebted for the loan of the few articles which you see before you to-night. Mr. Moore, at a time when his firm had already attained that unique position in the economic and social life of New York which they now occupy, recognised that they were in the habit, as is still the case with even the more important silversmiths of this country, of confining their designs for domestic table-ware to the few patterns which in the course of time have come to be considered as standard. Spoons and forks, for instance, were invariably modelled on the lines of the old fiddle pattern, the king pattern or the beaded, and, as is invariably the case when monotonous repetition prevails in a craft, that which originally may once have possessed some meaning and some beauty of its own had become a mere lifeless, senseless copy, with the vices of the original intensified and its virtues rendered of no avail.

Almost from the first Mr. Moore succeeded in imparting to the work of his firm a virtue which I venture to think has been its leading characteristic ever since. And here again I must point out that in this he was but reflecting the spirit of his age and country. We may say what we will about American art work; we may abuse it (and in many cases we are perfectly justified in doing so) as being vulgar and *outré*; we may accuse it (and with justice) of an uneasy restlessness, which detracts to a large extent from its undoubted originality and cleverness; but in ninety-nine out of a hundred cases we find that it possesses the redeeming quality of interest. In no other branch of American art, and in no other American craft, is this quality more patent than in the silverwork. This, I take it, is the chief lesson which our silversmiths on this side of the Atlantic have to learn from America. Let me take as an illustration the most common and ordinary articles of household use. The peculiar qualities of silver, its malleability, its ductility, its practical freedom from oxidation, and its indifference to the action of certain acids, render it not so much a luxury as a necessity for certain of our household utensils. Even the most economically-minded householder must therefore reckon among his belongings a certain number of silver spoons and forks. The intrinsic value of the metal would lead one to suppose that a certain amount of additional cost, in respect to the manual labour of fashioning it, might well be bestowed upon it. The articles which are made from it, and of which I now speak, will last more than one lifetime, and are constantly and recurrently put before our eyes morning, noon and night. It would certainly seem, therefore, that we are not asking too much if we demand from those who are responsible for its production a certain amount of individuality and freshness of design as well as technical skill and soundness of workmanship. But in England there exists among trade silverworkers, as I have already hinted, a more than slavish adherence to tradition

and a slothfulness of mind, as it were, which no other craft can parallel. The spoons with which I eat my soup in my house I find reproduced in all their clumsy, heavy artlessness at the house of the neighbour I visit to-morrow, and were I to dine out in this England of ours on 300 of the 365 evenings of the year, I doubt whether in the whole of that time I should handle more than three distinct patterns of silver plate. In America the case is far different, in that one finds in a majority of households a display of table ware which has been constructed to an original and a unique design. Not that each one has his table ware made specially to order, but the varied assortment of trade patterns of silver ware which are found not only at Messrs. Tiffany's, but at half a dozen other silversmiths' establishments in New York, Philadelphia and Boston, renders it easy for the householder to choose some such variation from the standard and accepted shapes as will reflect more or less his own idiosyncrasy. Thus one finds that a New York dinner-table has something to attract one's attention and call forth either admiration or the reverse, while it gives also some clue, however slight, as to the presence or absence of artistic taste and knowledge on the part of one's host. I want to say, and I must make a little brief excursion from my main subject to say it, that I expected to be able to show you to-night a representative collection of ordinary domestic American silverware. I had relied upon the kindness of the London representative of Messrs. Tiffany, but I had, in a measure, reckoned without my host, for I had forgotten the disabilities imposed upon a foreign workman by the legal trammels restricting the sale of silver in this country. Messrs. Tiffany are unable to keep on hand any of their more worthy examples, and what they have been kind enough to send to-night consist merely of a few odd pieces, which are but random and far from representative examples of their workshops. To these a friend has kindly added one or two pieces of ordinary domestic ware and ornaments. I should like you, however, at the close of my random little talk, to examine for yourself this simple spoon and fork, which is apparently, as I hold it up, a mere variation upon one of our English stock shell patterns. Closer examination, however, will convince you that there is a distinction as well as a difference, and that the distinction is on the side of the American. It has what our similar pattern entirely lacks—proportion, subtlety and grace of line, and plain as it is the perfection of modelling. From the practical point of view, too, it holds its own against its European competitor; it is well balanced and "holds itself," if I may so express it, in the hand in a manner which could only be the result of thought and intelligent care on the part of its modeller. Take again this little oyster fork, which requires a somewhat closer examination to reveal its good qualities. It is more ornate, but it is not on that account that I value it. I saw not long ago, in the shop of a West-End London silversmith, a collection of table ware which was much more elaborate and much more expensive than this little piece, but the engraving and the modelling of those English examples were, as compared with this, heavy, clumsy and almost vulgar. They entirely missed the virtue which this, and which, indeed, the majority of American work, possesses, of being essentially silver and nothing but silver. I mean by this that there is in every metal an inherent meaning and capacity which, beyond everything, should control the designer. The design which is perfectly proper and fitting for silver should strike us as manifestly out of place and inharmonious if applied to any other metal possessed of widely differing qualities. This to many of you present to-night will sound as the veriest truism—and so it is. Yet it is a truism which seems to be a heresy in the eyes of some English silversmiths.

(To be continued.)

The County Council Hall.

SIR,—It appears that the Council are still undecided upon the site for their intended new hall. The last recommendation of their committee, which the Council referred back to them for further information, was of a site on the west side of Parliament Street, between Great George Street and the Government offices, the cost of the acquisition of which was apparently to be three-quarters of a million.

On the same day by another decision the Council (unless circumstances should cause them to change their resolution) deferred the accomplishment of that great metropolitan improvement, the opening of a thoroughfare between Holborn and the Strand, until a date the arrival of which is by no means certain, and is regarded with very different degrees of satisfaction by different members of the community, and by some with feelings far apart from satisfaction.

The site for the County Hall, which is now relegated to further consideration, is, without doubt, a dignified one; but I

think it cannot be said to have any particular claims on the ground of convenience, nor does it appear to be conspicuously economical.

I think, moreover, it is a pity, and it is to point out this that I now address you, that a previous recommendation or suggestion of the Improvements Committee of the Council should be lost sight of. When that committee reported on the scheme for opening a road between Holborn and the Strand, it was one of their recommendations of the scheme that the sloping terrace, by which it was proposed that the junction between the new street and the Strand should be formed, would afford a splendid site for a central, convenient and commanding County Hall. This appears to me to be a suggestion altogether undeserving to be overlooked. From the point of view of convenience a better position than this could scarcely be found, in the midst of the principal thoroughfares and close to the Law Courts and the busiest part of the area under the Council's administration. Certainly Parliament Street will not bear comparison with it in this respect.

Looking at the Strand in its present condition it is true that the site of Holywell Street would hardly be recommended for a building intended to make a dignified impression, but it must be remembered that one object in the Council's scheme for a new street—of equal importance with the provision of accommodation for traffic—was the improvement of the Strand by the demolition of the southern side of Holywell Street, so leaving a broad road north of the churches bounded by the sloping terrace already referred to. Then certainly there will be no lack of dignified accessories to the position.

On the practical ground of economy also, considering that in the construction of the new street and the carrying out of the suggested improvements great expense would be incurred, whether the Council availed themselves of the site they would thus provide or not, I expect that this site would prove to have the advantage over its competitors.

The new street, with the consequent improvement of the Strand, has apparently been put off indefinitely, but it is so important, if not so absolutely necessary, that it is likely to be undertaken even before the day now looked for by the Council, if that should be long delayed, and then the problem of finding a place for the County Hall is solved.

Under such circumstances the Council would, I should think, be well advised to deliberate long before giving their approval to any other site for their hall and incurring the very heavy cost of a suitable building adequate for their accommodation.—Yours obediently,

H. P. BURKE-DOWNING, F.S.I., A.R.I.B.A.

175 Strand, London, W.C.:

June 20, 1893.

GENERAL.

The Annual Conversazione of the Society of Arts is announced to take place on Friday evening, June 30, at the Imperial Institute, South Kensington. The bands of the Scots Guards and the Royal Artillery will perform a selection of music in the gardens, which will be specially illuminated, and the galleries of the Institute, containing the Colonial and Indian collections, will be open for inspection.

The Arnold Local Board of Health have appointed Mr. F. W. Jackson, F.S.I., of Nottingham, their surveyor, in the place of his father, Mr. F. Jackson, C.E., F.S.I., lately deceased, who for a period of thirty-five years held the appointment.

Karl Schlesinger, who was a prominent member of the Düsseldorf school, and produced several excellent landscape and genre paintings, died last week in his sixty-seventh year. He was a native of Lausanne.

Bedingham Castle, in Essex, which is one of the historic residences in England, with a demesne of 2,000 acres, was offered for sale on Tuesday, but the property had to be withdrawn owing to the absence of bidders.

Mr. G. McCredie, Architect, of Sydney, has been elected a member of the New South Wales Parliament for the division of Central Cumberland.

Mr. Henry Gill, the builder and head manager of the Berlin Waterworks, died in Berlin on Saturday, aged sixty-nine. He was born in England.

Professor Curtis began a series of practical demonstrations in forestry at Earl's Court Exhibition on Saturday.

Mr. J. W. Trounson, F.R.I.B.A., F.S.I., Penzance, has been appointed architect for the enlargement of St. Paul's Church, Penzance.

Mr. T. B. Richards, M.S.A., F.S.I., architect and surveyor, has removed his office from 25 Bedford Row, W.C., to Bedford Row Chambers, 42 Theobald's Road (first floor), nearly opposite his former office.

Mr. Charles Barry has been appointed by the Plymouth Corporation assessor in the competition plans for the Prince Rock, How Street and Looe Street schemes for the housing of the working classes.

The Architect.

THE WEEK.

THE death occurred on June 21 of HUBERT JANITSCHKE, the learned professor of the history of art in the University of Leipzig. He was born at Troppau, Moravia. After the varied studies which are gone through by all Germans who are ambitious to become professors he spent a long time in Italy studying the examples of all classes of art which remain there. Then he put his knowledge to a test by serving as assistant in a museum. He was afterwards elected professor of the history of art in Prague. He filled a similar office in Strasburg, and on the death of ANTON SPRENGER he was transferred to Leipzig. He translated some of the minor writings of LEON BATTISTA ALBERTI. Among his writings are books on the Renaissance of Italy, Dutch painting, essays on ANDREA DEL SARTO, JEAN BELLINI, TINTORETTO, PAUL VERONESE, DANTE and GIOTTO. Of late years Professor JANITSCHKE was an invalid, but he bravely continued his teaching in spite of his sufferings.

WÜRZBURG, which is the subject of two of PROUT'S illustrations lately published in this Journal, is of much importance in the ecclesiastical history of Germany. The Irish missionary, St. KILIAN, laboured in the district, and the town became a bishopric in the middle of the eighth century. Most of the important buildings of Würzburg were erected for ecclesiastical purposes. The exhibition of archaeological objects and works of art which is to be opened in the great hall of the Academy of Music on August 6 should, on account of the antiquity and wealth of Würzburg, be filled with much that will be interesting. Visitors can then trace the extent of the development of Franconian art during a thousand years. During the greater part of that period the bishops were the rulers of the district, and they were able to expend large sums of money on promoting the arts. The exhibition will only remain open during four weeks.

AMONG the treasures possessed by the Royal Irish Academy is a manuscript in a metal case known as the "Domnach Airgid," or silver reliquary. It was purchased from an old woman in the county of Fermanagh by a shrewd bookseller, who sold it for 300*l*. The manuscript is a part of a Latin version of the Gospels; and archaeologists of repute, among them EUGENE O'CURRY and GEORGE PETRIE, believed that it dated from the fifth century and belonged to St. PATRICK. The judgments of deceased archaeologists are, however, rarely accepted as infallible by their successors, and the manuscript and its shrine have been of late years subjected to a new investigation. As regards the latter, all that can be ascertained is that it probably belonged in the eleventh century to the diocese of Clogher. But there is no evidence that it was made to hold the manuscript, and nothing to show when it was first employed for that purpose. Time and damp have made the vellum leaves adhere so closely that only a few pages could be examined. The aid of the experts of the British Museum was recently invoked, and as a result a great part of the manuscript has been disunited and can be deciphered. It is now believed that the writing was done in the eighth or the beginning of the ninth century, and is the work of a scribe who was ignorant and careless. From the character of the letters, as well as from the peculiarities of the version that was followed, it is concluded that he could not have been a contemporary of St. PATRICK. Although manuscript and shrine apparently are of different ages and have no relationship, we suppose the Council of the Academy will not place them apart in sections of their museum. Who knows whether at a later time it may not be again decided that the vellum and metal have kept company for a thousand years at least?

THE system of M. EUGÈNE HERMITE will be employed in connection with the sanitary arrangements of the International Exhibition of Hygiene, which is to be held at Havre in August. It consists, as some of our readers are aware, in the employment of sea-water which has gone

through a process of electrolysis as a disinfectant. M. HERMITE claims that the fluid when so treated is able to destroy completely or to change the character not only of organic matter in a state of putrefaction, but the most offensive gases. What is more important is that germs which are the most tenacious of vitality, such as the typhoid bacteria, are unable to withstand the prepared sea-water. The discoverer's experiments have been verified by the French Conseil Supérieur d'Hygiène, and the fluid has been largely used in Havre and elsewhere with good results. M. HERMITE proposes that in towns near the sea prepared sea-water should be laid on to all houses like potable water or gas. In towns more remote a substitute can be found by adding chlorine in some convenient and inexpensive form to ordinary water, which is then conveyed to the apparatus for electrolysis and goes through the treatment adopted with sea-water. So many wonderful schemes for dealing with sewage have turned out failures, people will not readily believe that M. HERMITE has solved the most difficult of sanitary problems without wider experience of the results. The investigation which his discovery will receive at Havre will therefore be watched with attention.

WHEN the London School Board proposed obtaining plans by competition from unofficial architects for a school to accommodate twelve hundred children, we pointed out that the indefiniteness of the site was a drawback. After several months' deliberation it has been decided to fix on a site in the Fulham Palace Road as the most suitable. The competition will therefore refer to a school in that position for 1,200 children, showing means of enlargement to accommodate 1,600 children, with all necessary classrooms, teachers' rooms, staircases, cloakrooms and lavatories. In the event of the plan of a three-storey building being adopted, a separate hall must be provided for each of the three departments; but in the case of a one-storey building, one hall only need be provided for the use of the whole school; the planning to be subject to, and in conformity with, the rules and regulations of the Education Department. The plan is to embrace a drawing classroom, so arranged as to be accessible both for boys and girls, and with this exception no special or technical classrooms are required. A teacher's residence is not to be provided, but a schoolkeeper's house must be shown, also playgrounds and boundary walls. The designs are to be sent in between the 8th and 15th of September, 1893, both days being inclusive. The competitor whose design is placed first in point of merit by the assessor shall be paid a premium of 150*l*.; the competitor whose design is placed second shall be paid a premium of 100*l*.; and the competitor whose design is placed third shall be paid a premium of 50*l*. The first premiated design shall be the property of the Board, and all other designs shall be returned to their respective authors immediately after the public exhibition of the competitive designs, which the Board reserve the right to hold during a period not exceeding two months from the date of the award. The competitor to whom the first premium is awarded shall, in the event of the Board erecting the school shown on his plans, be employed as architect, and shall be paid in accordance with the schedule of professional charges published by the Royal Institute of British Architects, such payment being additional to the premium of 150*l*. Mr. J. MACVICAR ANDERSON will be the professional assessor. The following will be deemed by the assessor to be grounds for disqualification, viz.:—Any attempt on the part of a competitor to make known his identity, or to influence the decision of the assessor, personally or through any member of the Board or otherwise. The delivery of a design after the specified time, unless arising from accident in transmission, explained to the satisfaction of the Board. Any encroachment, however slight, beyond the limitations of the site as laid down and figured on the plan supplied. Non-compliance with the conditions respecting the drawings required, whether as to the number, scale or style of execution. Material excess of cost in the opinion of the assessor beyond the outlay that would be sanctioned by the Education Department. Departure from or non-compliance with any of the conditions embodied in the instructions, the whole of which will be rigidly adhered to and enforced.

WORKING DRAWINGS.*

IN the pages of the handbook on the preparation of working drawings we find much of what CARLYLE calls "that kind of knowledge which holds good in working," and to which nature is supposed to say, "Yea! yea!" Everybody knows, or ought to know, that many drawings which are considered satisfactory have to undergo various changes before the subjects are realised in materials. It does not always happen that the extent of the operations is acknowledged by those who perform them or is recognised by the original designers. But the fact remains that little things as well as big, girders, no less than tiles and wall-papers, can only be made when the drawings are treated in a manner which the workmen can understand and which corresponds with the processes to be employed. To a great extent in England the adaptation is kept secret.

With the sort of teachers, superintendents and examiners by whom the system of the Government schools of art are kept going for their own advantage, it is impossible to expect that anything relating to the business of a factory or a workshop can count for much. Pretty drawings are got up by the students, and it is supposed that work can be executed from them. It is not believed that when any of the drawings are employed by manufacturers, who wish to flatter the authorities, they have to be transformed, unless in those cases where the artists happen to be attached to workshops and adopt a sort of treatment that cannot be called official. In the first contribution in the book before us—that is, on "Carpet Designing"—the author, Mr. A. MILLAR says:—"It is of the greatest importance that a carpet designer should have the power of indicating form by mass instead of by outline, and this faculty is rarely met with in this country, probably owing to the method of teaching in favour at most of our schools of art. I have never yet met with a designer wholly trained under the system in force there, who had the power of indicating light and shade by solid distinct masses of colour." Mr. MILLAR, like many other simple people, is under the delusion that the schools should have some connection with manufacturers; he does not see that the fine gentlemen who work them take a more exalted and personal view of what is needed, and that for amateurs, who have to prepare reports, outlining is easier to deal with than masses of colour. That French carpet designers "have the power of representing by blotches of colour a perfectly-modelled flower or scroll, with lights, shadows and affected lights," does not concern the officials; they have not to design or weave carpets, and besides flowers, lights and shadows were long ago excommunicated by aid of departmental canons. Mr. RATHBONE also, in his essay on metal-work, refers to "those errors of construction which make the British (or other) workman scratch his head and wonder why designers were created for the apparent purpose of setting him problems which he can never solve," but what signifies the puzzles of workmen so long as South Kensington flourishes and the statistics in the blue-books relate to millions of figures?

The information contained in the volume published by Messrs. BELL & SONS can do much to enable designers to come nearer in touch with the workmen. The pages reveal many things which are now held to be trade secrets. A man can never make entirely satisfactory working drawings unless he has had more or less acquaintance with workshop practice, and thus in his mind's eye can see the materials that are to be employed and the processes to which they are to be subjected. Unfortunately too many draughtsmen are never able to get beyond the pictorial or representative qualities of their drawings, and cannot adequately realise all that their lines should mean. It is not possible for any book to enable mental deficiencies of that kind to be wholly overcome. There must be sufficient contact with objects until they become realities to the mind. Several of the authors who have united in composing the essays on practical design admit the limitations of their ability to explain. But they have done something which will make up for the shortcomings of the art schools and of most of the treatises on design. A designer who

has followed the advice of the writers will not appear as an amateur to any workman into whose hands his drawings may fall.

The titles of the essays will suggest the range of the volume, and it will be observed that the authors can claim to be accepted as specialists, viz.:—"Carpet Designing," by A. MILLAR; "Woven Fabrics," by A. SILVER; "Pottery," by W. P. RIX; "Tiles," by OWEN CARTER; "Metal-work," by R. LE B. RATHBONE; "Stained-glass," by SELWYN IMAGE; "Drawing for Reproduction," by GLEESON WHITE; "Bookbinding," by H. ORRINSMITH; "Printed Fabrics," by A. SILVER; "Floorcloths," by A. SILVER; "Wall-papers," by G. C. HAITÉ. The explanations in the essays are made clear by aid of diagrams and illustrations which are as practical as the text. Authors and publishers have supplied a volume that is worth far more than the price charged.

The advice is conveyed in the simplest and most explicit manner, and there is so much of it that extracts can be selected with difficulty. A part of Mr. SELWYN IMAGE'S essay, relating to a church window with a single figure, may, however, serve as a sample:—

Let us take next a piece of white endless cartoon paper, and draw on it in black chalk an outline of the lancet window which we have to fill, of the exact sight-size and shape. For a small window like this we may get the paper strained on a stretcher; that will make our work pleasanter no doubt. In the case of large windows, however, it is more convenient for the people at the glassworks not to have the cartoon on a stretcher; for a design of any considerable size, therefore, I would remember this, and make the drawing on a piece of paper pinned against a large board or against the wall, rolling it up from time to time at either end as may be necessary in the course of working at it. A very little practice will enable us to draw under these conditions quite easily and pleasantly enough; and we shall save the men at the glassworks, as I have said, not a little inconvenience.

Well then, we have traced out in a black chalk line the shape of the window. A quarter of an inch within this all round draw another line, and fill up between the two with black chalk; this thick black line represents the external border of lead. And here, let me say that wherever any lead is to come in the window I represent it on the cartoon by a black chalk line such as I have described, a quarter of an inch wide.

Between the stonework of the window and the coloured glass (in order slightly to detach the design from the wall) there always must run what is called a "white line;" a very narrow border, that is, of plain white glass. I represent this in the cartoon by leaving a border of white paper, rather wider than a quarter of an inch, next to the external border of lead; and this white border is itself edged on the other side by a lead, drawn, as always, a quarter of an inch wide. Then the entire space enclosed by the inner of these two lead lines is the space we have to fill with our design.

In the window before us, we said that we should put the figure of a saint. I will make this figure as large as the space will conveniently allow. Taking a piece of charcoal, then, I draw the figure in from my sketch, being above everything careful to get its proportions, masses and main lines satisfactory; and, for this purpose, constantly standing at a good distance from my cartoon, and looking at it reversed in a glass, so that I may see it as a whole. When I have got the figure in this way to my mind, I will draw in and model very carefully the head, the hands and the feet; and then enclose each of these with a lead line. . . . I should then go on to trace carefully the outline of the whole figure and the forms of the drapery, wherever the edges of it come (as, for instance, in the turnover of a sleeve), and to enclose these with a lead. We shall have got in this way the entire figure drawn, with such of the leads as are absolutely necessary in their places. Now let us join these latter to one another, with straight leads running horizontally and perpendicularly across the figure and sometimes at a slight angle for variety's sake. One can lay down no absolute rule at this point, the thing must be left to the designer's fancy at the moment; all that one can say is, keep the pieces of glass of a simple shape, of a fairly varied shape, and small in size.

The youngest student will be able to understand suggestions which are given so plainly, and throughout the pages there is no less care in avoiding all obscurities of diction. Every one of the writers could join with Mr. HAITÉ in saying, "I have sought honestly to place the practical experiences of a number of years at the disposal of the student—experiences which came to me gradually, and by the closest possible application." The book can be taken as supplementing the different treatises on ornament. It does not deal with styles except in regard to their fitness for execution. The writers wisely keep within prescribed limits, and in doing so they have been able to render more service to students than if they entered on disquisitions about theories of ornament and the like. They have attained a completeness that is remarkable considering the size of the book. The work will be useful to designers who wish to keep to one branch of manufacture, or to those who are trying to prepare themselves in order to be equal to all

demands that may arise. Any among them who desire to produce drawings for the illustration of books or periodicals will find ample instructions in the editor's paper on "Drawing for Reproduction."

AN ARCHITECT'S ESSAYS.*

IN one of the essays which Mr. WHELAN has reprinted he says, "I used to work ; now I gossip." The words may be taken as a key to the contents of the small volume. An architect in successful practice cares only about expressing his thoughts on drawing-paper, at least in this country ; and very few names of men who received commissions for building are to be found in any catalogue of books. When an architect becomes a writer he must feel like a man who employs a foreign language in composition. He may use the words correctly and with skill, but in his heart he is sure to wish that he was allowed to show his power in an exercise with which he was more familiar. Mr. WHELAN'S gossip is very pleasant reading, which can have interest for many readers besides architects, but it would be better if the qualities which are partially revealed in the gossiping could be utilised for the benefit of the world by employing building workmen rather than compositors. The author does not believe that a paper or printed speech can alone reveal the thoughts that arise in us, for, as he says, "The arts are only different methods of expression ; their mother-idea is in its essence the same, though the children thereof may be poems or painting, melodies or architecture." Apparently Mr. WHELAN could employ more than one of those methods with skill, but at present he is satisfied, and it is a pity, to be a gossip.

In this rôle he does not forget, probably it would be impossible, that he is an architect. He is not, however, shoppy, nor does he make himself ridiculous, like some men, in seeking the sympathy of the world because the supremacy of the profession is not admitted on all sides, and he is nowhere pedantic. By nature Mr. WHELAN was made an observer and thinker, but he must have regarded things and reflected on them in a different sort of manner if he had not received a training as an architect. Anyone who will take note of Mr. THOMAS HARDY'S respect for shadows when describing a place (to mention only one peculiarity of his novels) must see that the writer was at one time enjoined to "think in shadow" when designing. Still more evident is the link which unites Mr. WHELAN to architecture, for it appears in parts where it was not expected. Thus, when speaking about a part of Derbyshire, he says:—"One couchant rock, blue-black, mysterious, dominates the Dale down to Derwent Valley. This gloomy monster is, I am convinced, an ancient dragon. His comparatively modern name is Hu Gare: romantic enough ; but what it may have been I know not when, in forgotten æons, he fought his brethren in the slime. I would now, however, build a deeply-founded castle on his back, and thus, like a tiger-moth to cardboard, pin him to his upland for ever." The suddenness of the transition from palæontology to building produces some of the effect of wit. In another place, when referring to "the subtle bonds which unite the moods of man and of nature," he gives an architectural illustration which, to many readers, will appear as daring as novel:—

We understand the language of our painters and our poets, but do we quite understand the voice (mute, yet eloquent) which discourses passionate love in the tendrils of hard stone, and thrills us with echoes of romance from mountains building-crowned and sea-set gems of art ? The men of the Middle Ages loved nature with a love as intimate, though differing in form of expression, as any modern. But, intense as was their love, it was practical and energetic ; to them a lovely knoll existed that it might be perfected by a still more lovely tower, which should gather to itself all the force and beauty of the surrounding landscape ; to them a fertile plain, with its level lines, was a foil for the rocket-like upspringing of many hundred feet of tapering stonework ; to them a river-brightened valley was made to be the haunt of monasteries, whose carved capitals and spandrels should repeat the herbage and flowers, even as the translucent stream did in its own sweet but different way. And when nature, as in Mont St. Michel, put on a more daring mood than usual, the poet-builders caught her spirit and outdared her own audacity.

An architect will divine from the foregoing extract that Mr. WHELAN is a Gothicism, or as he describes himself, was

"suckled in the creed, nowadays forlorn, of Mediævalism." He has much to say which is subtle about the builders of that time, as when in his essay on "The Glory of Heights" he tells us:—

A feeling of humour, almost mad, strengthened in the builders as they left the earth. Sardonic faces began to grin down on the underlings : relentless gargoyles prepared themselves to splash the pavement-haunting burghers. But the designers ever had the sense of plumb descent before them. Their weird creations were often winged and always of the tribe of sprites ; they could fear no fall. When the half-human demon of Notre Dame who sneers upon Paris was first brought from the gates of hell, he was guarded by a parapet. The figures of the pious oxen, in the open pinnacles at Laon, stare from between close ranged columns. Because they had rushed of their own will from the plain to be harnessed to the cathedral stones, their secular safety was made sure. Should they go mad with height they could not leap down. It is evident that the architects of old knew that until the ordinary mortal is gifted with wings the terror of sheer descent will shake his nerves almost to dissolution. The instinct of ascent, especially characteristic of the plain-dwellers, found complete satisfaction in the Middle Age. This instinct allied itself with a much nobler emotion. The national impulse, encouraged by religion, embossed the great shield of Christendom with fretwork of spires ; the blazonry stretches from the sub-tropic South to sub-arctic Norway. Viollet le Duc relates that there was certainly much rivalry between city and city as to the loftiness of their respective fanes ; at Beauvais ambition overleaped itself remarkably. But it is not for us to criticise these gifts of the kings. We may struggle on a fugitive page to fix for a moment our light-hearted opinions on their life's work ; they with inspired chisel struck an authentic idea into vital stone.

One essay is devoted to "The Gothic Renaissance," and the credit for the revolution which is signified by the phrase is ascribed to AUGUSTUS WELBY PUGIN. Whatever shortcomings we may find in his buildings, and it must be admitted they have as little repose about them as PUGIN himself, nobody can deny that he exercised a mysterious influence over his contemporaries. The man who in a few years after his change from Protestantism presumed to lecture Roman Catholic bishops and priests on theology, while he was supposed to carry out an engagement to give instruction in architecture, who was patronised by ecclesiastics after he had described the sanctuary of the principal church in London as corresponding with the proscenium of a theatre—nay, after declaring St. Peter's to be a mass of imposition and the city of the Popes as miserable, disgusting and depressing, and, a greater feat still, who was able to move the placid GILBERT SCOTT for once into a state that might be called enthusiastic—is not to be judged by the rules which govern everyday people. Look at the difference in the productions of Birmingham before and after PUGIN'S designs were employed there, and his potency will be manifest. In the exhibition of 1851 it was the Pugin or Mediæval Court which saved England. We must remember, too, that he received no training from a master. Whatever he knew he taught himself, for all his easy-going father could do for him was to allow him to see how drawings for engravers could be produced. In exercising his influence there was no diplomacy about PUGIN. He cared as little for a manufacturer as for a prelate, Roman or English, and he never disguised his contempt of men or things. People were allowed no time to controvert his theories ; they seemed to be subjected without resistance. Even the Office of Works was subdued by him, and he was permitted to confine luckless theological students at Maynooth in cells that would excite mutiny in a penal settlement. It is no wonder the Irish priests come out of them more inimical to England than when they entered. In spite of such defects, which arose from want of experience, PUGIN'S work is marvellous in quantity and variety, and in being produced by his own right hand. Yet he lived barely more than forty years. He had exhausted himself by the time other men have finished the preparation for a career. It must be acknowledged that few have cared to uphold PUGIN'S reputation, and Mr. WHELAN is courageous in writing so much in his favour. In spite of neglect, he has so much faith in his idol's magnanimity, he imagines that PUGIN would look favourably upon most things if he were able to have another glimpse of England.

Were Pugin now among us, as he very well might be, what would he think of the last forty years of architectural endeavours ? He would see that the seed he sowed had not altogether fallen on sterile soil. He would recognise on the whole a higher aim of effort, a more complete realisation. He would probably regret a latitudinarianism in selection of types to be followed, and a license in the seizure of forms more striking than beautiful ; but his mellowed judgment would likely condone the weakness that attends upon fashion : he would

* *An Architect in Exile ; and other Essays.* By Bernard Whelan. London : Burns & Oates, Limited.

confess that sky-lines are governed by laws similar to those which distribute dress improvers. He would admit, as something to be reckoned with, the longing for a new thing, which, from the time of the Athens of St. Paul, has irked the minds of men. He would pardon a little extravagance if he saw it mingled with a little sincerity. He would be told the Houses of Parliament, with which he had so much to do, were still the mural crown of a triumphant race. He would meet his contemporary Pecksniff flourishing anew in Piccadilly Circus. He would praise countless country mansions and town houses that are not without an intimate charm of their own. He would the better understand the Renaissance reaction when he gazed upon the Law Courts. He would find less stupidity, more imagination, less carelessness; he would welcome the signs of improvement, slow but steady, which, amid stress and struggle, point to a better architectural future.

Another worthy, who was far better disciplined and was without any trace of PUGIN's theatricalness, viz. WILLIAM BURGESS, is also lauded by Mr. WHELAN. He expresses only an opinion that is now general among architects when he says:—"Even if one disliked a style, one could begin to love it if it gave us such a man as BURGESS. It is a little less than a national catastrophe that no great building of his is always before the eye of the public—such a building as he would have raised where Mr. STREET's Law Courts now stand."

The place of exile to which Mr. WHELAN is doomed appears to be "a quiet corner of Kent." Many toilers in London offices during sultry days will envy his lot, for "within a few miles are Hever Castle, Penshurst Place, and Knole House." He can also gaze upon brickwork which does not appear odious to nature, for in some examples "kindly winters and amorous summers have dyed them deeper than richest peonies." In such a place there is a chance for meditative moods, and a man who can produce such a collection of essays as accompany "An Architect in Exile" should be able to derive compensation for temporary withdrawal from practice. Let us hope the little volume is only a forerunner of many others, for a more frank and genial pocket companion on a holiday tramp is not easily discovered in the libraries.

WESTMINSTER ABBEY.

THE following protest has been issued by the Society for the Protection of Ancient Buildings:—
